Cell Dev. Biol.* 9:772077. doi: 10.3389/fcell.2021.772077

Background: HAUS6 participates in microtubule-dependent microtubule amplification, but its role in malignancies including colorectal cancer (CRC) has not been explored. We therefore assessed the potential oncogenic activities of HAUS6 in CRC.

Results: HAUS6 mRNA and protein expression is higher in CRC tissues, and high HAUS6 expression is correlated with shorter overall survival in CRC patients. HAUS6 knockdown in CRC cell lines suppressed cell growth *in vitro* and *in vivo* by inhibiting cell viability, survival and arresting cell cycle progression at G0/G1, while HAUS6 over-expression increased cell viability. We showed that these effects are dependent on activation of the p53/p21 signalling pathway by reducing p53 and p21 degradation. Moreover, combination of HAUS6 knockdown and 5-FU treatment further enhanced the suppression of cell proliferation of CRC cells by increasing activation of the p53/p21 pathway.

Conclusion: Our study highlights a potential oncogenic role for HAUS6 in CRC. Targeting HAUS6 may be a promising novel prognostic marker and chemotherapeutic target for treating CRC patients.

Keywords: HAUS6, tumor growth, proliferation, p53/p21 pathway, survival

BACKGROUND

Colorectal cancer (CRC) is one of the leading causes of mortality worldwide (Chouinard et al., 2013). Progression from microscopic pre-neoplastic lesions to larger adenomas involves a cascade of mechanisms including tumor suppressor gene mutation and bypass of cell cycle checkpoints (Fakih, 2015). Unfortunately, current treatment strategies have low success rates due to our poor understanding of the molecular mechanisms behind CRC progression. Hence, there is an urgent

Abbreviations: CRC, colorectal cancer; EGFP, enhanced green fluorescent protein; FJTCM, Fujian University of Traditional Chinese Medicine; FACS, fluorescence activated cell sorting; HAUS6, HAUS augmin like complex subunit 6; MT, microtubule; NEDD1, neural precursor cell-expressed developmentally down-regulated protein 1; RT-PCR, quantitative reverse transcription - polymerase chain reaction; 5-FU, 5-fluorouracil; p-TNM, pathologic tumor-node-metastasis; TMA, tissue microarray; SPF, specific pathogen-free.

demand to understand the fundamental mechanisms underlying CRC development and to find novel molecular targets (Vescovo and MA, 2015).

Follow-up analysis of gene expression profile microarrays from our previous study (GEO Submission: GSE113513) (Shen et al., 2019) showed that levels of mRNA encoding HAUS6 are higher in CRC tissues than in adjacent noncancerous colorectal tissues. Our preliminary experiments further suggested that HAUS6 knockdown inhibits growth of CRC cells in culture (data not shown). These results suggest that HAUS6 has oncogenic potential in CRC.

HAUS6 is one of the 8 subunits of the augmin complex (Goshima et al., 2008; Zhu et al., 2008), which is required for microtubule (MT)-dependent MT amplification during cell division independently of the centrosomes and chromatin (Lawo et al., 2009; Du et al., 2011; Nakaoka et al., 2012; Hayward et al., 2014). HAUS6 promotes MT-dependent MT amplification by interacting with and recruiting neural precursor cell-expressed developmentally down-regulated protein 1 (NEDD1), a subunit of the NEDD1- γ -tubulin ring complex. Depletion of HAUS6 reduces MT density in the bipolar spindle (Zhu et al., 2008). Dissociation of the augmin complex or the presence of HAUS6 and/or γ -tubulin reduces MT formation and MT bundling, thereby affecting spindle assembly during mitosis and MT organization in interphase (Goshima and Scholey, 2010; Sá nchez-Huertas et al., 2016). MTs, spindle poles and chromosomes form the main elements of the spindle architecture (Kline-Smith and Walczak, 2004; Meunier and Vernos, 2012), which plays an essential role in organizing bipolar spindles and chromosomal segregation during mitosis (Nakayama et al., 2013). Failure of these processes results in mitotic arrest and apoptosis and contributes to chromosome mis-segregation and aneuploidy, a hallmark of cancer (Holland and Cleveland, 2012). However, the role of HAUS6 in cancer has never been evaluated to our knowledge. In the present study, we investigated the effects of HAUS6 expression on patient prognosis and on viability and proliferation of CRC cell lines *in vitro* and *in vivo*, as well as its potential underlying mechanisms.

MATERIALS AND METHODS

Bioinformatic Analysis

HAUS6 expression in CRC and noncancerous colorectal tissues was compared using the Oncomine database (www.oncomine.org), as described previously (Shen et al., 2019) (**Supplementary Table S1**). Correlation of HAUS6 expression with CRC patient survival was performed using the R2 Bioinformatic Platform (<http://r2.amc.nl>), as described previously (Shen et al., 2019). The threshold of significance was set at $p < 0.05$.

Patients and Specimens

Both CRC and matched adjacent non-cancerous tissues were collected from 36 CRC patients admitted to the First People's Hospital Affiliated with Fujian University of Traditional Chinese

Medicine (FJTCM). Clinicopathologic characteristics of patients are summarized in **Supplementary Table S2**. No patients received radio- or chemotherapy prior to surgery. Tissues were snap-frozen and stored in liquid nitrogen for quantitative RT-PCR or processed for immunohistochemistry. Samples were stained with hematoxylin and eosin, and then examined by experienced pathologists, who assigned pathologic tumor-node-metastasis (p-TNM) grades according to International Union Against Cancer guidelines.

In addition, cDNA from 80 primary CRC and 15 adjacent noncancerous colorectal tissues were obtained from the cDNA-HCoLA095Su01 tissue cDNA array (Shanghai Outdo Biotech, Shanghai, China; **Supplementary Table S3**). A further 280 primary CRC and 260 adjacent noncancerous colorectal tissues were obtained from the tissue microarray (TMA) (Shanghai Outdo Biotech; **Supplementary Table S4**).

Quantitative RT-PCR

Cells and tissue samples were lysed with RNAiso Plus reagent (Takara, Beijing, China) and total RNA was extracted according to the manufacturer's instructions. A total of 1 μ g RNA was reverse-transcribed into cDNA using PrimeScript RT reagent kit (Takara, Beijing) and RT-qPCR was performed using SYBR Premix Ex Taq (Takara, Beijing) and the ABI 7500 Fast Real-Time PCR System (Applied Biosystems, Carlsbad, CA, United States) according to manufacturer protocols. Primer sequences against HAUS6, TP53, CDKN1A and GAPDH are shown in **Supplementary Table S5**. GAPDH was used as an internal control.

Immunohistochemical Staining

Tissues were processed using routine immunohistochemistry methods as in our previous study (Shen et al., 2019). Tissue specimens collected in our laboratory were fixed, sectioned and stained with primary antibodies against HAUS6 and Ki-67 then secondary biotinylated antibody (**Supplementary Table S6**), followed by incubation with horseradish peroxidase-conjugated streptavidin (Maixing, Fuzhou, China). Background staining was assessed by omitting the primary antibody. Five randomly selected fields were examined using a Leica microscope (Wetzlar, Germany) at $\times 40$ magnification.

For tissue arrays, slides were incubated with primary antibody against HAUS6 (dilution 1:500, Abcam, United Kingdom) as described (Wang et al., 2014; Shen et al., 2019). Images were captured using a Nano Zoomer 2.0 HT slide scanner (Hamamatsu Photonics, Hamamatsu, Japan) and processed using Nano Zoomer Digital Pathology View 1.6 software. Staining intensity and the percentage of positively stained cells were determined as described (Huang et al., 2016; Shen et al., 2019). Protein expression was calculated by multiplying the intensity and percentage scores together, giving expression scores ranging from 0 to 12.

Survival Analysis

The median HAUS6 expression in CRC tissues was used as the cutoff to divide tumors into "low expression" or "high expression". The relationship between HAUS6 expression and

overall survival was analyzed using Kaplan-Meier curves and the log-rank test.

Cell Culture

Human CRC cell lines HCT116, HCT-8, HT-29, Caco2 and RKO were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). Human colon cell line FHC (ATCC No. CRL-1831) was purchased from the American Type Culture Collection (Maryland, United States). Wild-type HCT116 cells (HCT116/p53^{+/+}) and p53 knockout HCT116 cells (HCT116/p53^{-/-}) were a gift from Dr. Yao Lin (Fujian Normal University, Fujian, China) and originally obtained from Dr Bert Vogelstein (Johns Hopkins University, Baltimore, MD). All human cell lines have been authenticated using STR (or SNP) profiling within the last 3 years has been included. RKO, HCT116, HCT-8, Wild-type HCT116 cells (HCT116/p53^{+/+}) and p53 knockout HCT116 cells (HCT116/p53^{-/-}) cells were maintained in RPMI1640 (Thermo Fisher Scientific); HT-29 cell in M5'A medium (KeyGEN); Caco2 cells in DMEM (Thermo Fisher Scientific); and FHC cells in DMEM supplemented with 10 mM HEPES (for a final conc. of 25 mM), 10 ng/ml cholera toxin, 0.005 mg/ml insulin, 0.005 mg/ml transferrin and 100 ng/ml hydrocortisone. All media contained 10% FBS (Thermo Fisher Scientific), 100 U/ml penicillin, and 100 mg/ml streptomycin (Hyclone) at 37°C in a humidified atmosphere of 5% CO₂. Cells were verified using short tandem repeat genotyping and examined for *mycoplasma* contamination using RT-PCR.

5-FU (Sigma-Aldrich) was dissolved in DMSO and final concentration of 2.5 μM used to treat control and HAUS6 knockdown cells for 24h; DMSO was used as a vehicle control.

Lentiviral Transduction

Lentiviruses encoding shRNA against HAUS6 or CDKN1A or encoding control shRNA (**Supplementary Table S7** for sequences) and enhanced green fluorescent protein (EGFP) under control of the CMV promoter were obtained from Shanghai GeneChem (Shanghai, China). CRC cells were transduced with lentivirus at a multiplicity of infection (MOI) of 10 for 72 h before analysis. To examine effects of HAUS6 over-expression on cell proliferation, HT-29 cells were transduced for 72 h with a lentiviral vector (MOI = 10) encoding full-length human HAUS6 (2,946 nt, GenBank accession NM_017645; Shanghai GeneChem). Transductions were selected for 2 weeks using 1 μg/ml puromycin.

Cell Viability Analysis

Cell viability was measured every day for 5 days by CCK-8 assay. Briefly, transduced cells were reseeded into 96-well plates at a density of 2,000 cells/well with 100 μl medium/well. CCK-8 dye (10 μl, Cell Counting Kit-8, Abbkine, Wuhan, Hebei, China) was added to each well and cells were incubated for 2 h at 37°C. Cell viability was measured at 450 nm.

Cell Survival Analysis

Transduced cells were reseeded into 12-well or 6 well plates at a density of 500 or 1,000 cells/well and incubated for 10–12 days at 37°C under 5% CO₂ in a humidified incubator. Colonies were

fixed with 4% paraformaldehyde for 20 min and stained with 0.1% of crystal violet for 20 min. Colonies were photographed and the number of colonies counted. Data were normalized relative to control cells.

Cell Cycle Analysis

Transduced cells were collected and fixed with cold 70% ethanol at 4°C overnight. The cells were then washed three times with PBS and incubated with FxCycle PI/RNase Staining Solution (Thermo Fisher Scientific) for 30 min. Fluorescence-activated cell sorting was performed using fluorescence activated cell sorting (FACS) Caliber (Becton Dickinson, San Jose, CA, United States), and ModfitLT version 3.0 (Verity Software House, Topsham, ME, United States) was used to analyze the cell cycle based on DNA content in different phases.

In Vivo Experiments

Male pathogen-free athymic nude mice (6–8 weeks old) were purchased from Shanghai Laboratory Animal Co., Ltd. (Shanghai, China) and maintained in a specific pathogen-free (SPF) facility.

Transduced CRC cells (1×10^6) in 100 μl RPMI-1640 medium containing 50% matrigel were subcutaneously injected into the flank of nude mice ($n = 8$). Tumor growth was monitored from day 7 after injection on every second day for 19 days. Tumor volume was calculated as $(1/2) (\text{length} \times \text{width}^2)$, where length and width refer to the longest longitudinal and transverse diameters.

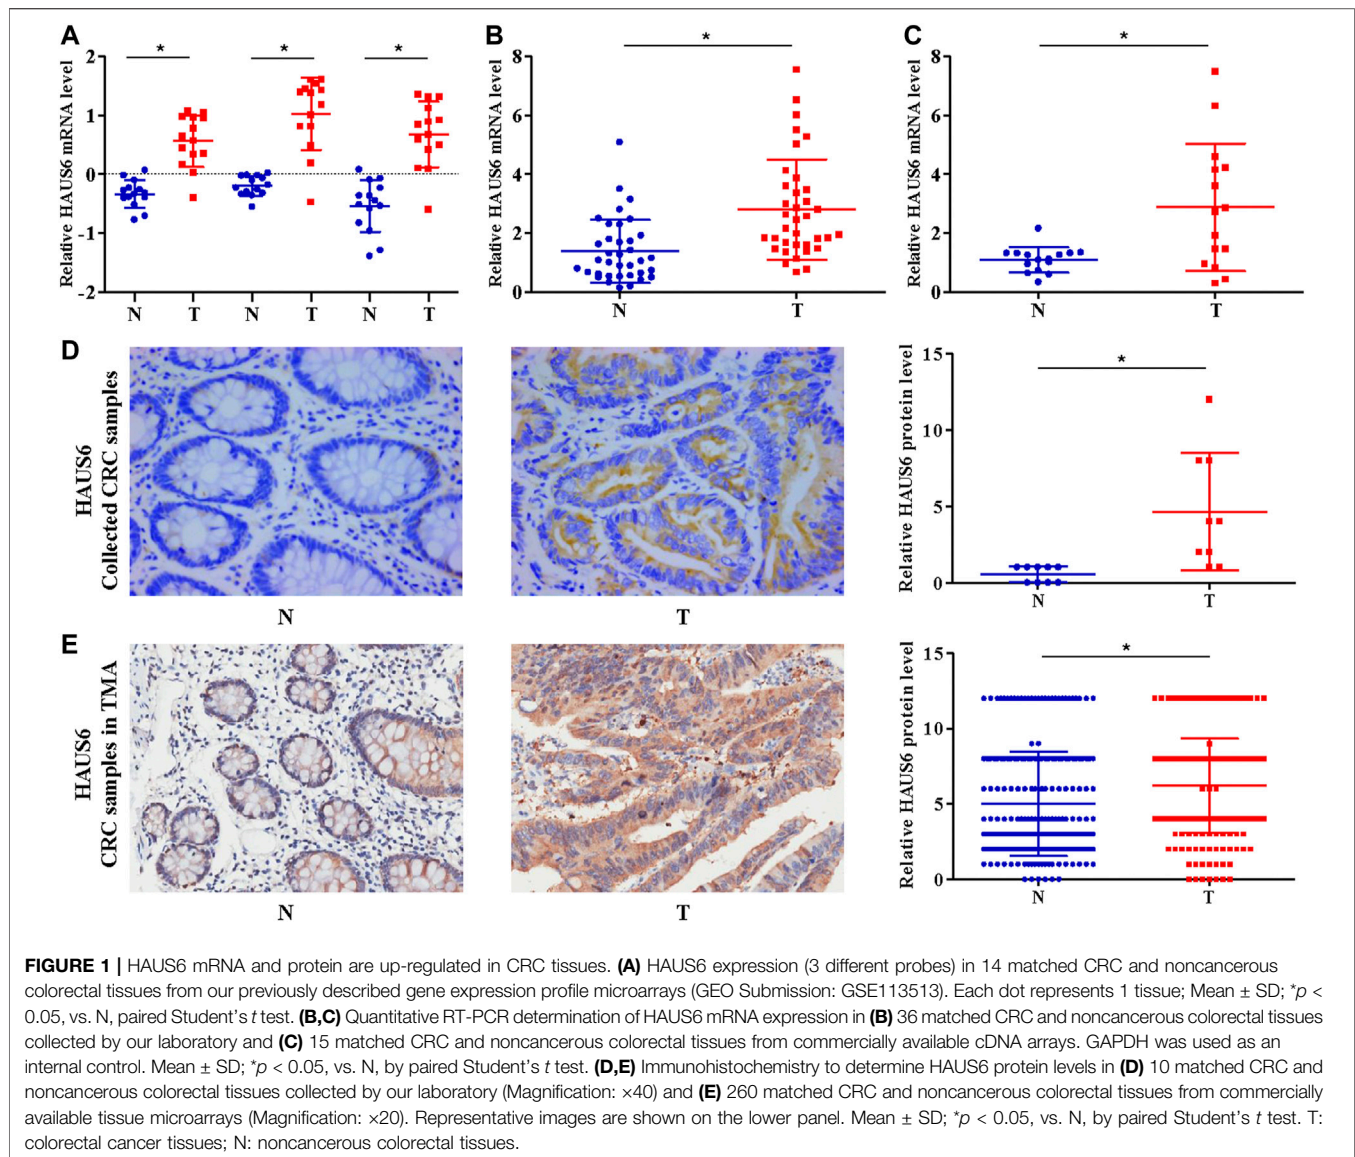

Tumor growth was also measured in terms of GFP intensity using an IVIS Spectrum whole live-animal imaging system (PerkinElmer, Waltham, MA, United States). Mice were anesthetized with isoflurane and sacrificed by neck dislocation on day 26 after injection, and tumors were dissected and weighed. Collected tissues were processed for immunohistochemistry.

Microarray Analysis

HCT116 cells were transduced with lentivirus encoding shRNA specific for HAUS6 or control shRNA for 72 h. Briefly, total RNA was extracted with Trizol reagent (Thermo Fisher Scientific) and analyzed by CapitalBio (Beijing, China) using the human GeneChip Primeview array (Affymetrix, Santa Clara, CA, United States) according to the manufacturer's instructions. Microarray images were scanned using GeneChip Scanner 3,000 and analyzed using GeneChip GCOS 1.4 software (Affymetrix). Genes with a p -value < 0.05 and fold change >2 were defined as differentially expressed. The raw microarray data can be found in the NCBI Gene Expression Omnibus (GEO: GSE140326). Enriched pathways in DEGs were identified using KEGG pathway enrichment analysis.

Western Blot Analysis

Cells were lysed with RIPA lysis buffer (Thermo Fisher Scientific) and the protein concentration was determined using BCA assay (Thermo Fisher Scientific). The proteins (50 μg) were then separated by SDS-PAGE and transferred onto a nitrocellulose membrane. The membranes were blocked with BSA (Sigma Aldrich) and incubated overnight at 4°C with primary

antibody against HAUS6, p53, or p21 (**Supplementary Table S6**). The membranes were then washed three times with TBST (5 min per wash), and incubated at room temperature for 1 h with horseradish peroxidase-conjugated goat anti-rabbit (CST, United States). The blots were visualized using enhanced chemiluminescence (Thermo Fisher Scientific) according to the manufacturer's protocols. Band intensities were quantified using ImageLab software. The expression of GAPDH was used as a control. Three independent experiments were performed for each assay.

Statistical Analysis

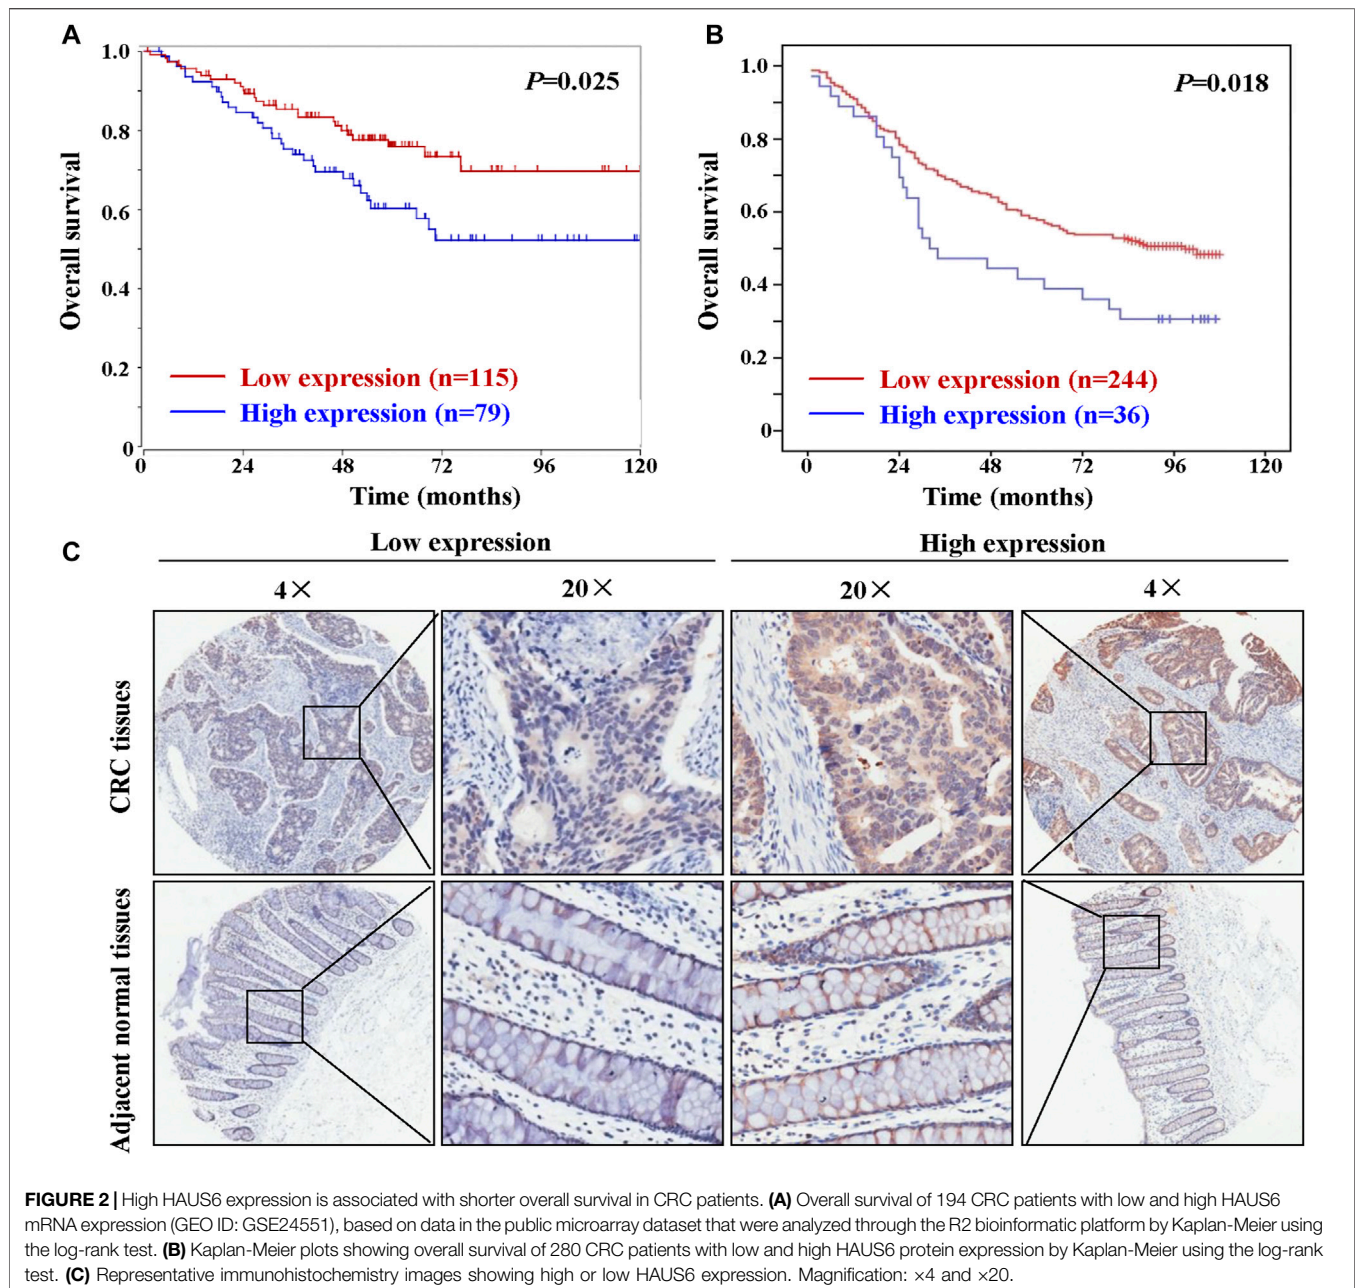

Statistical analysis was performed using SPSS 20.0 (IBM, Chicago, IL, United States). Data are presented as mean \pm SD. Differences between two groups were assessed using the independent or paired Student's t test, while differences among three or more groups were assessed using one-way ANOVA. Survival

differences were assessed using the log-rank test. The correlation between HAUS6 and CDKN1A expression was analyzed using Pearson's correlation. A p -value of <0.05 was considered statistically significant.

RESULTS

HAUS6 is Highly Expressed in CRC Tissues

We first compared HAUS6 expression in cDNA samples from 14 matched pairs of primary CRC tumors and non-cancerous tissues from a cDNA array (GEO Submission: GSE113513). HAUS6 expression was higher in CRC tumors than non-cancerous tissues (**Figure 1A**). Analysis of publicly available tumor expression data from the Oncomine database (<http://www.oncomine.com/>) also showed higher HAUS6 mRNA levels in CRC tissues than non-cancerous tissues (**Supplementary Table**

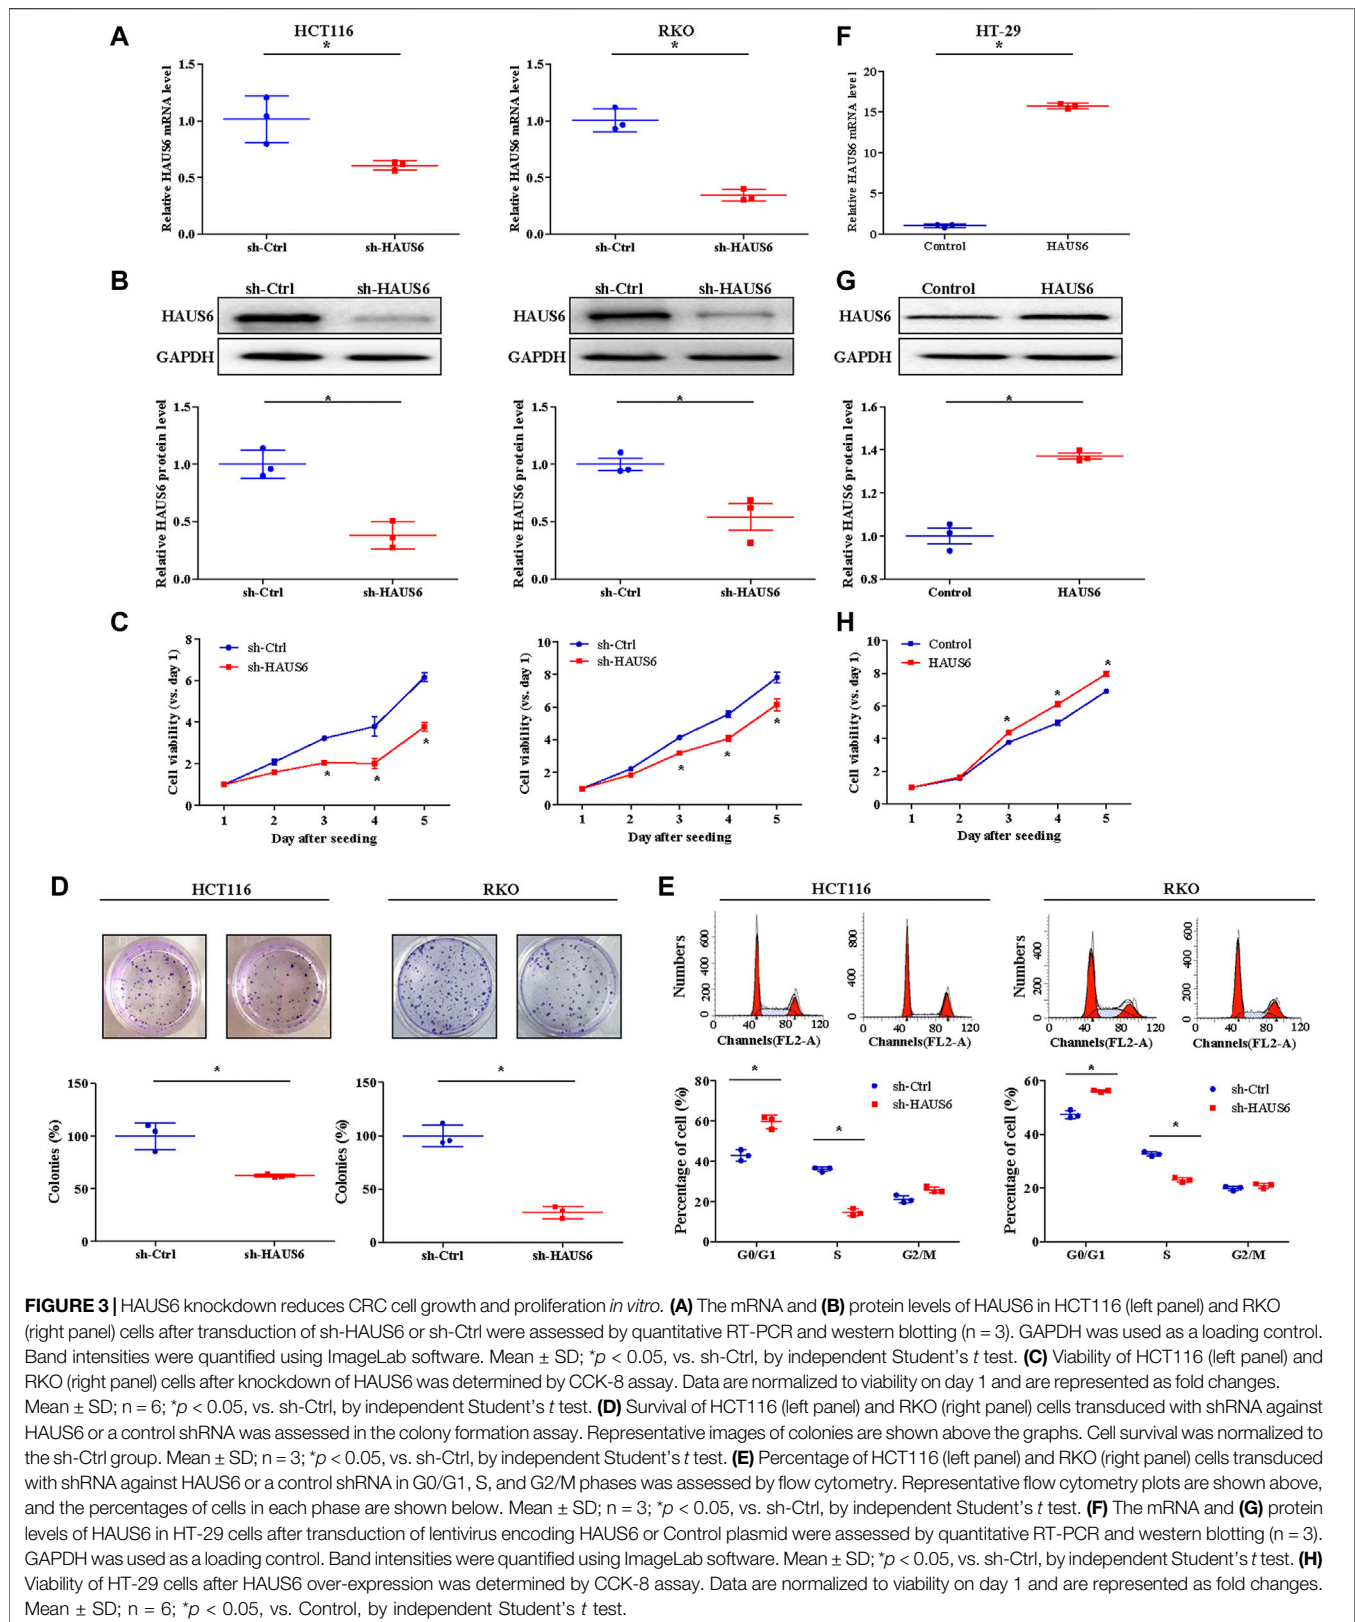

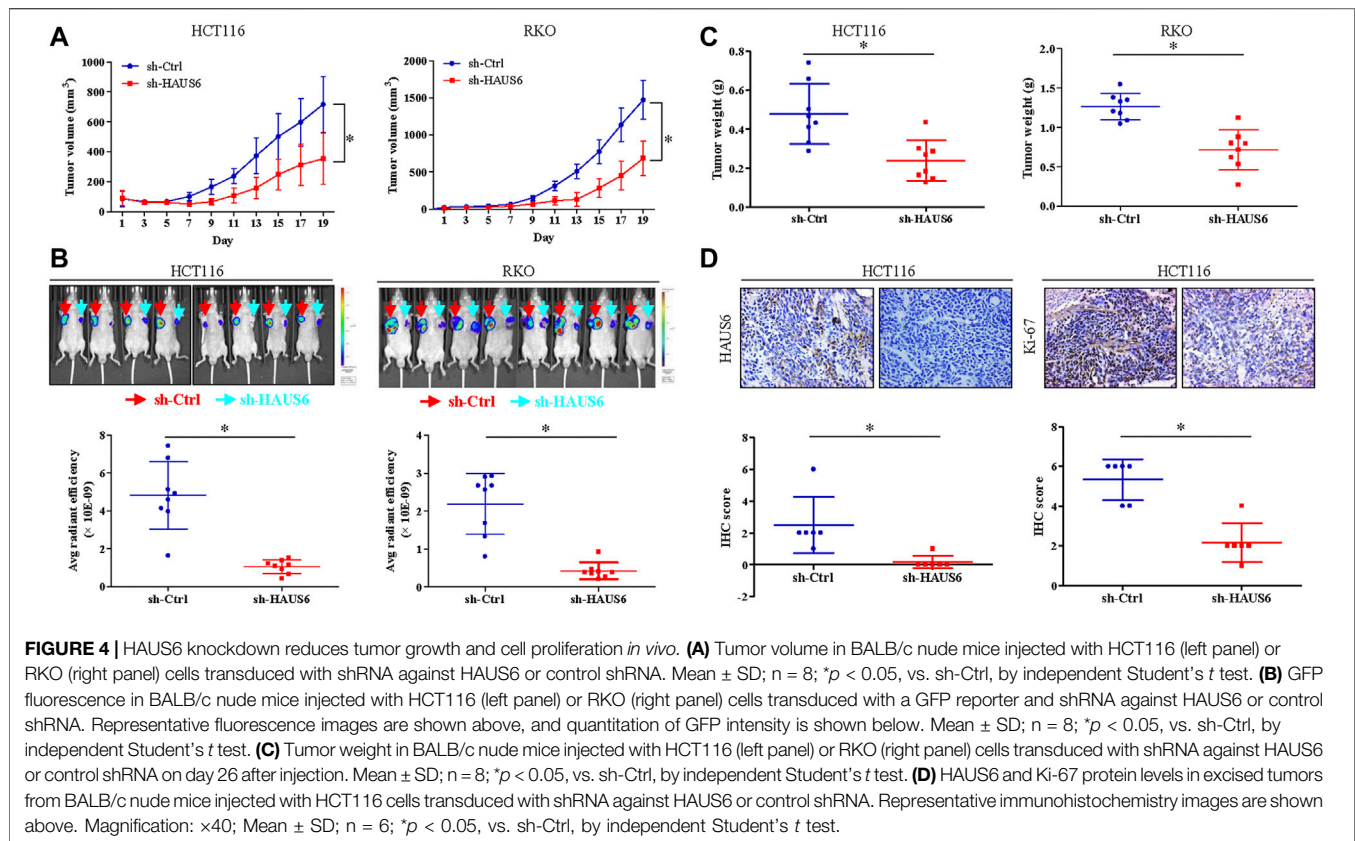

S1). Quantitative RT-PCR analysis of HAUS6 expression in clinical samples of 36 CRC tissues and adjacent non-cancerous colorectal tissues from our laboratory and a cDNA tissue array containing 15 pairs of CRC primary tumors and surrounding non-cancerous tissues also showed higher HAUS6 mRNA expression in CRC tissues (Figures 1B,C). Immunohistochemistry of 10 pairs of CRC samples randomly selected from the above mentioned 36 pairs, as well as analysis of a tissue microarray of 260 pairs of CRC samples

(Shanghai Outdo Biotech), confirmed that HAUS6 protein levels were higher in CRC primary tumor tissues (Figures 1D,E).

HAUS6 Expression is Associated With Poor Patient Prognosis

Kaplan-Meier analysis of 80 patients whose primary tumor tissues were sampled on the cDNA array mentioned above did

not reveal any difference in patient survival between tumors with low and high HAUS6 mRNA expression (data not shown). In contrast, analysis of data from 194 CRC patients (high expression: n = 79; low expression: n = 115) from the public microarray dataset using the R2 bioinformatic platform showed that high HAUS6 mRNA expression was associated with shorter overall survival (Figure 2A). Similarly, tumors with high HAUS6 protein levels were associated with shorter overall survival in 280 CRC patients (Figure 2B; high expression: n = 36; low expression: n = 244). Representative images of high or low expression of HAUS6 in CRC tissues are shown in Figure 2C.

HAUS6 Knockdown inhibits CRC Cell Growth and Proliferation *in Vitro*

In cultured RKO and HCT116 cells, which constitutively express relatively high levels of endogenous HAUS6 (Supplementary Figure S1A), we assessed the effects of HAUS6 knockdown on growth and proliferation of CRC cells. Lentiviral transduction with vectors expressing short hairpin (sh)RNAs against HAUS6 down-regulated HAUS6, as expected (Figures 3A,B; Supplementary Figures S1B–C). CRC cells transduced with HAUS6 shRNAs had lower cell viability than those transduced with control RNAs (Figure 3C; Supplementary Figure S1D). Moreover, HAUS6 knockdown also decreased the number of colonies formed by CRC cells

(Figure 3D). Cell cycle analysis revealed that HAUS6 knockdown increased the percentage of cells in G0/G1 and decreased the percentage of cells in S phase (Figure 3E). However, HAUS6 knockdown did not affect cell apoptosis in HCT116 cells (Supplementary Figure S2). In contrast, in HT-29 cells which exhibits relative lower expression of HAUS6 (Supplementary Figure S1A), lentiviral transduction with vectors over-expressing HAUS6 up-regulated HAUS6 protein expression, and increased the cell viability of HT-29 cells based on the CCK8 assay (Figures 3F–H).

HAUS6 Knockdown Suppresses CRC Cell Growth and Proliferation *in Vivo*

We next used a xenograft mouse model to assess the effects of HAUS6 knockdown on CRC cell growth and proliferation *in vivo*. HAUS6 knockdown strongly reduced tumor volume (Figure 4A) and decreased fluorescence of tumor cells (Figure 4B) in nude mice injected with GFP-expressing CRC cells. Final tumor weights were also lower in mice injected with HAUS6 knockdown cells than in those injected with control cells (Figure 4C). Immunohistochemistry of the excised tumors showed that Ki-67 protein expression was decreased in HAUS6 knockdown cells (Figure 4D), suggesting that HAUS6 knockdown suppresses CRC tumor growth by inhibiting cell proliferation.

HAUS6 Knockdown Suppresses Cell Proliferation by Down-Regulating p21

Microarray analysis of HAUS6 knockdown HCT116 cells revealed a total of 274 differentially expressed genes (DEGs) in CRC (**Figures 5A,B**; GEO Submission: GSE140326). CDKN1A (encoding p21 protein) was upregulated in HAUS6 knockdown cells (**Figure 5C**), and this was confirmed in both HCT116 and RKO cells by quantitative RT-PCR (**Figure 5D**) and western blotting (**Figure 5E**). Transduction with shRNAs specific for HAUS6 significantly up-regulated p21 protein expression, which were reversed after CDKN1A knockdown in HCT116 cells (**Figure 5F**). Functionally, HAUS6 knockdown decreased cell viability and colony formation, whereas CDKN1A knockdown had the opposite effect and attenuated the effects of HAUS6 knockdown (**Figures 5G,H**). HAUS6 knockdown increased the percentage of cells in G0/G1 and reduced the percentage in S phase, which were reversed by CDKN1A knockdown (**Figure 5I**). Analysis of microarray expression data (GEO Submission: GSE113513) showed that CDKN1A was down-regulated in CRC tissues (**Figure 5J**) and its expression correlated negatively with HAUS6 expression (**Figure 5K**).

HAUS6 Knockdown Suppresses Cell Proliferation by Activating the p53 Pathway

KEGG pathway enrichment analysis of DEGs in HAUS6 knockdown cells identified the p53 pathway as the one of the most enriched signalling pathways (**Figure 6A**). Given the key regulatory effects of p53 on cell proliferation and CDKN1A transcription, we next explored the effect of HAUS6 on the p53 pathway. HAUS6 knockdown increased TP53 expression in HCT116 and RKO cells at the levels of mRNA (**Figures 6B,C**) and protein (**Figure 6D**). The inhibitory effects of HAUS6 knockdown on cell viability were attenuated by knockout of p53 (**Figures 6E,F**) or treatment with the p53 inhibitor PFT- α (**Figure 6G**). Similarly, p53 knockout blocked the inhibitory effects of HAUS6 knockdown on cell survival (**Figure 6H**) and cell cycle progression (**Figures 6I,J**). To determine the molecular mechanism by which HAUS6 knockdown regulates p53, we evaluated p53 protein stability in RKO cells expressing wild-type p53. Protein levels of p53 and its downstream p21 decreased over time in sh-Ctrl cells, but remained stable after HAUS6 knockdown (**Figure 6K**).

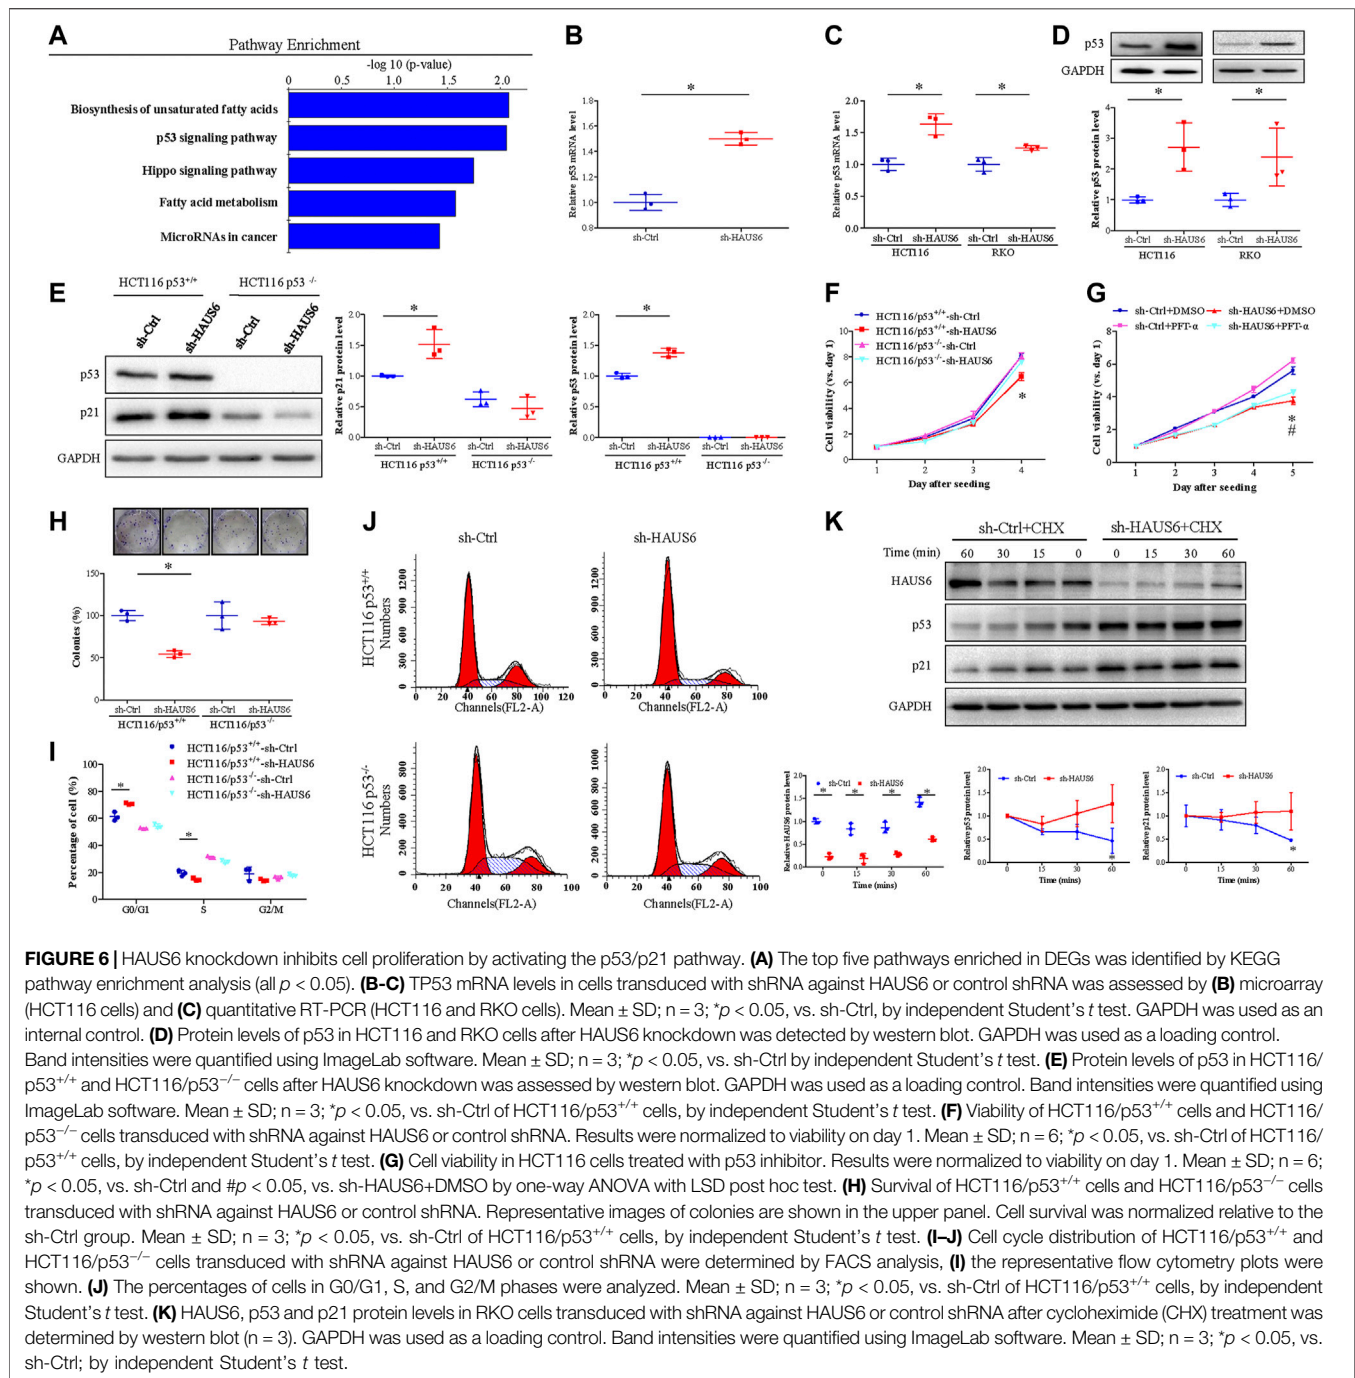

HAUS6 Knockdown Enhances 5-Fluorouracil Treatment on Suppressing Cell Proliferation by Activating the p53/p21 Pathway

We further assessed the effect of HAUS6 on the response of CRC cells to 2.5 μ M 5-fluorouracil (5-FU) treatment for 24 h. Transduction of sh-HAUS6 or 5-FU treatment down-regulated HAUS6 and up-regulated p53 and p21 protein expression. These effects of HAUS6 knockdown were further enhanced after combined with 5-FU treatment (**Figure 7A**). Moreover, HAUS6 knockdown or 5-FU treatment reduced viability of HCT116 cells, and combination of them exhibited greater suppression on cell viability of HCT116 cells at different time points (**Figure 7B**). Moreover, combining HAUS6 knockdown with 5-FU treatment led to greater suppression of HCT116 colony formation than HAUS6 knockdown or 5-FU treatment alone (**Figure 7C**), as well as higher percentages of cells in G0/G1 and G2/M and lower percentage in S phase (**Figures 7D,E**).

DISCUSSION

In this study, we show that the spindle-associated protein HAUS6 has an oncogenic role in CRC. HAUS6 mRNA and protein expression were both increased in CRC tissues compared to adjacent noncancerous colorectal tissues, and higher HAUS6 expression was correlated with shorter overall survival in CRC patients. HAUS6 knockdown suppressed tumor growth by inhibiting cell viability and survival as well as by arresting cells in G0/G1, which were enhanced after combination of 5-FU treatment. HAUS6 knockdown exerted these effects by reducing p53 degradation and activating the p53/p21 signaling pathway.

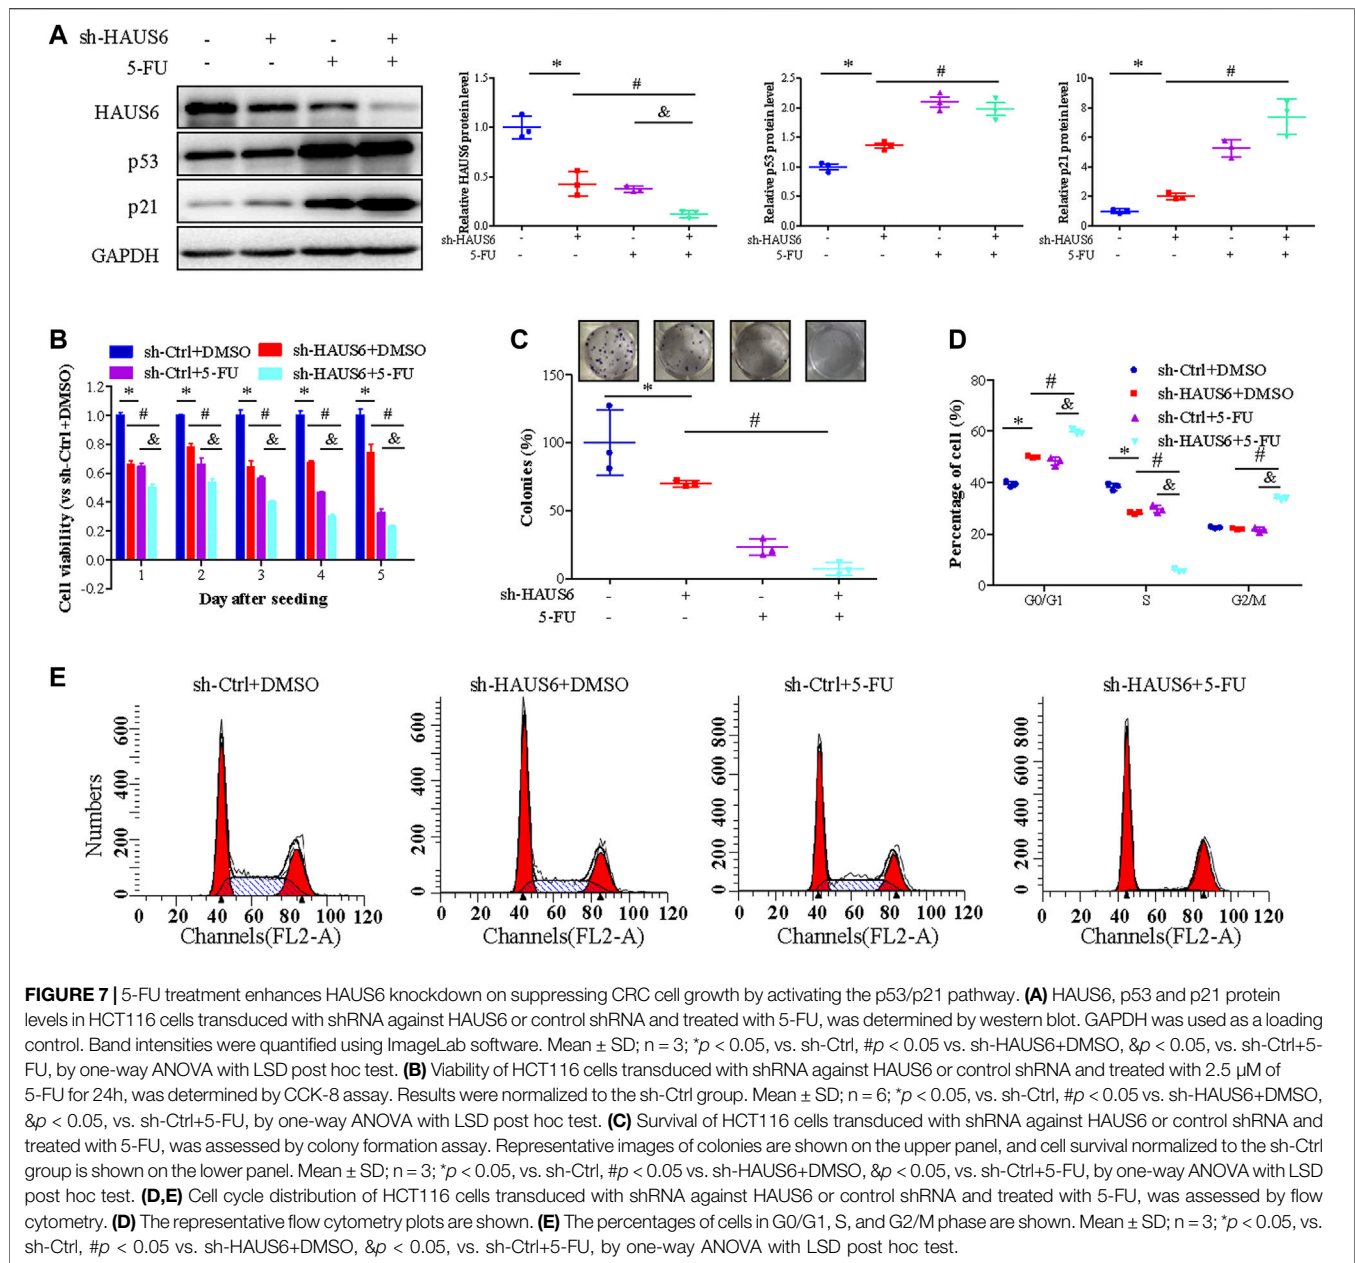

For the first time, we evaluated the clinic significance of HAUS6 in CRC. Analysis from our own cDNA array (Shen et al., 2019) found that HAUS6 mRNA expression was increased in CRC tissues compared to adjacent noncancerous colorectal tissues. This was consistent with our analysis of multiple datasets from the Oncomine database, quantitative RT-PCR analysis of a cDNA tissue array, and immunohistochemical analysis of a tissue microarray. These results suggest that increased HAUS6 expression may be common in CRC and may play an essential role in CRC development. Moreover, survival analysis revealed a correlation between high HAUS6 mRNA and protein expression and shorter overall survival in CRC patients. This demonstrates that HAUS6 may be useful as a biomarker for CRC prognosis.

However, HAUS6 expression should first be further investigated in other types of malignancies.

Due to the potential significantly value of HAUS6 in development and therapy of CRC, it's urgent need to investigate the biological function of HAUS6 in CRC. However, the biological function of HAUS6 in most malignant neoplasms (including CRC) remain largely unknown. Cancer cells are characterized by an uncontrolled increase in cell proliferation (Sherr, 1996; Yuba-Kubo et al., 2005), which requires mitotic spindle formation. Nucleation of MTs is the initial step of mitotic spindle formation

(Holland and Cleveland, 2012; Nakayama et al., 2013), and loss-of-function in MT-dependent MT amplification results in mitotic arrest (Jang et al., 2016). Therefore, inhibition of mitotic spindle formation by targeting microtubule nucleation factors may be a promising anti-cancer strategy (Karna et al., 2011; Bates and Eastman, 2017; Kollareddy et al., 2017; Paier et al., 2018). Many microtubule inhibitors, e.g. taxans, vinca alkaloids and paclitaxel, induce mitotic arrest by interfering with microtubule dynamics and have been used to treat cancer (Taylor et al., 2008; Ehrhardt et al., 2013; Po'uha and Kavallaris, 2015). However, due to side effects in normal

cells and acquired resistance in cancer cells, it is important to further explore the underlying mechanism. Series of functional study show that knockdown of the spindle assembly factor HAUS6 suppressed tumor growth *in vivo* and *in vitro* by inhibiting cell viability, survival and cell cycle progression. In contrast, HAUS6 over-expression obviously increased cell viability of HCT116 cells *in vitro*. We further show that HAUS6 knockdown enhanced the ability of 5-FU to decrease cell viability and survival and to arrest cells in G0/G1 and G2/M phases. These results suggest that HAUS6 may be a promising new target for anticancer treatments.

The potential of HAUS6 serving as a therapy target encouraged us to further explore its underlying mechanism on suppression cell growth in CRC. Microarray analysis of HAUS6 knockdown cells revealed 103 up-regulated genes and 171 down-regulated genes.

Many of them, including CDKN1A (Lodygin et al., 2002), CyclinD1 (Wang et al., 2018), ROCK2 (Li et al., 2017) and HMG2 (Gao et al., 2017), have already been implicated in proliferation and cell cycle progression. One notable DEG was CDKN1A (p21), which arrests cell cycle progression at G1/S phase by binding to and inhibiting cyclin-dependent kinases (Harper et al., 1993). We found that p21 protein levels were increased in HAUS6 knockdown cells, and that CDKN1A knockdown reversed the effects of HAUS6 knockdown on cell viability, cell survival and cell cycle arrest. Moreover, HAUS6 expression was inversely correlated with CDKN1A expression. These results indicate that CDKN1A may mediate the oncogenic effects of HAUS6. However, the regulatory effects of HAUS6 on p21 need to be further explored.

To further explore its regulatory effects on related signalling pathway, KEGG pathway enrichment analysis of DEGs in HAUS6 knockdown cells showed that the p53 pathway was one of the most enriched. The p53 protein upregulates p21 in response to stress stimuli by binding to two highly conserved p53 response elements in the p21 promoter (el-Deiry et al., 1993; Jung et al., 2010). As a tumor suppressor, p53 is expressed at low levels under normal conditions due to MDM2, which mediates nuclear export of p53 and targets p53 for ubiquitination and degradation. Under stress conditions, p53 rapidly accumulates and activates p21 (Wade Harper et al., 1993; el-Deiry et al., 1993; Vogelstein et al., 2000). In our experiments, HAUS6 knockdown increased TP53 mRNA and protein expression. Knockout of p53 also abrogated the effects of HAUS6 knockdown on cell viability, survival and cell cycle arrest in HCT116 cells. Therefore, the suppression of tumor growth caused by HAUS6 knockdown depends at least partly on activation of p53. We further found that HAUS6 knockdown reduced the degradation of p53 and p21, suggesting a mechanism by which HAUS6 regulates p53.

Taken together, these results show that HAUS6 knockdown suppresses CRC tumor growth by increasing the stability of p53. Moreover, combining HAUS6 knockdown with 5-FU treatment led to even greater down-regulation of HAUS6 and up-regulation of p21 and p53 than HAUS6 knockdown alone, suggesting a common therapeutic mechanism. The effect of HAUS6 on tumorigenesis and p53 expression is similar to that of Plk1, which recruits HAUS6 to spindle MTs and NEDD1 to the spindle and centrosomes during mitosis (Zhu et al., 2008). HAUS6 may therefore be a promising novel target for anticancer treatments. Further study should be done to investigate the mechanism by which HAUS6 knockdown activates the p53 pathway.

In summary, we show that HAUS6 upregulation is associated with shorter survival of CRC patients and increased cell viability in cultured CRC cells, while HAUS6 knockdown inhibits tumor growth and enhances 5-FU treatment by activating the p53/p21 pathway. HAUS6 may be a useful prognostic marker and chemotherapeutic target in CRC.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: NCBI [accession: GSE140326].

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by The specimens were used with written informed consent from the patients and approval by the local Ethics Committees. The patients/participants provided their written informed consent to participate in this study. The animal study was reviewed and approved by the Animal Committee of FJTCM.

AUTHOR CONTRIBUTIONS

JP and AS conceived and designed the experiments. LyL, YH, and ZS conducted bioinformatic analyses. MW and YC provided the reagents. XW, AS, XL, and XC determined HAUS6 expression in CRC samples. LL, YC, JC, YH, and LW performed biological function analyses *in vitro*. LyL, YH, ZS, MW, XC and XW performed animal experiment. TS, QZ, JP, and AS conducted rescued experiment. AS, XL, YC, LyL, and LL explored the underlying molecule mechanism. AS, JP, QZ, and LW conducted data analysis. AS, JP, and TS wrote and revised the manuscript.

FUNDING

This study was supported by the National Natural Science Foundation of China (81803882, 81673721, 81703913), the International Cooperative Project of Fujian Department of Science and Technology (2017I0007), and Natural Science Foundation of Fujian Province (2017J01846, 2020J06026).

ACKNOWLEDGMENTS
