The current standard treatments of glioma include surgical resection, supplemented with radiotherapy and chemotherapy, but the prognosis is poor. PARP-1 (Poly ADP-ribose polymerase 1) is a hot spot for cancer-targeted therapy and was reported to be significantly elevated in glioma. In this study, we analyzed the role of PARP-1 in DNA damage repair, constructed a PARP1-related DNA-repair prognostic signature (DPS), and screened targeted drugs for glioma. RNA-seq data of 639 glioma samples were downloaded from the GEO (Gene Expression Omnibus) database and divided into PARP1\_H and PARP1\_L according to the front and rear thirds of the expression level of PARP-1. First, we systematically analyzed the influence of PARP-1 on DNA damage repair, prognosis, and chemoradiotherapy sensitization of glioma. All glioma patients and patients with radiotherapy or chemotherapy had a better prognosis in PARP1\_L than in PARP1\_H. Next, differentially expressed DNA-repair related genes (DEGs) were identified between PARP1\_H and PARP1\_L by LASSO (Least Absolute Shrinkage and Selection Operator) Cox analysis and applied for constructing DPS. Based on the four-gene DPS, we then developed a new nomogram to assess overall survival in glioma patients. Additionally, PARP-1 was proved an effective target for glioma therapy. So, a series of computer-aided techniques, including Discovery Studio 4.5, Schrodinger, and PyMol, were applied for the virtual screening of favorable PARP-1 inhibitors. In conclusion, this study investigated the effect of PARP-1 on glioma prognosis and the sensitization effect of radiotherapy and chemotherapy, established a novel nomogram to evaluate the overall survival of glioma patients, and further explored targeted therapy for glioma.

## KEYWORDS

Glioma, PARP-1 (Poly ADP-ribose polymerase 1), DNA damage repair, Inhibitors, drug screening

## Introduction

Glioma is the most common primary intracranial malignancy. And current standard treatments include surgical resection, supplemented by radiotherapy and chemotherapy, but the prognosis is poor (Ames and Gold, 1991; Prokhorova et al., 2021). A lot of experience has been accumulated in tumor electric field therapy, immunotherapy, and targeted molecular therapy for glioma, but few results can truly change clinical practice (Stupp et al., 2017; Fangusaro et al., 2019; Hargrave et al., 2019; Reardon et al., 2020). Therefore, it is necessary to more accurately predict the prognosis of glioma patients and develop more effective treatments.

Genomic instability is one of the most prevalent features of tumor cells. It may be the combined effect of DNA damage, tumor-specific DNA repair defects, and failure to halt the cell cycle before the delivery of damaged DNA. Although these processes lead to genomic instability and disease processes, they also offer therapeutic opportunities (Lord and Ashworth, 2012) (Hannigan et al., 2013). DNA damage repair (DDR) determines not only the occurrence and development of tumors but also the sensitivity or tolerance of tumor cells to radiotherapy, chemotherapy, and other treatments that induce DNA damage. So, dysregulation of DDR pathways plays a significant part in tumor prognosis prediction and treatment. There are many ways of DDR, including nucleotide excision repair (NER), non-homologous end joining (NHEJ), homologous recombination (HR), mismatch repair (MMR), base excision repair (BER) (Figure 1), etc. DNA double-strand breaks are the most cytotoxic damage, and homologous recombination repair (HRR) is the most important and accurate repair method in DNA double-strand damage repair (Lord and Ashworth, 2012).

PARP (poly ADP-ribose polymerase) family are enzymes that catalyze the PAR modification of proteins and other substances (Kumar et al., 2020). Among them, PARP-1 was the most widely studied and played a key role in DNA repair pathways, especially in HRR (10, 11). When cellular DNA is damaged, PARP-1 responds immediately. It rapidly binds to the damaged DNA and catalyzes the decomposition of NAD<sup>+</sup> into nicotinamide and ADP (adenosine diphosphate). Then, ADP is linked to the self-modified region of PARP-1 and undergoes a complex reaction of poly-ADP-ribose to form PAR (Poly ADP-ribose). When reaching a certain length, the PAR poly chain dissociates from the DNA and then guides DNA repair enzymes such as XRCC 1 (X-ray repair cross-complementary gene 1) and DNA ligase III to carry out BER to remove the wrong or damaged bases (Gorren et al., 1997; Sandhu et al., 2013). Next, new single-stranded DNA fragments are synthesized by DNA polymerase and ligated with the original single-stranded

DNA by ligase to complete DNA damage repair (Ossovskaya et al., 2010).

Currently, the research reports on PARP-1 mainly focus on its expression and function in tumors lacking the BRCA1/2 gene, such as ovarian cancer, metastatic breast cancer, advanced prostate cancer, and pancreatic cancer (Ledermann et al., 2015; Robson et al., 2017; Golan et al., 2019; Abida et al., 2020). Recently, a study found that the expression level of PARP-1 mRNA in glioma cell lines was significantly increased, suggesting that PARP-1 is expected to become a new prognostic indicator for glioma patients and a new anti-glioma therapy target (Han et al., 2020).

In this study, RNA-seq data of 639 glioma samples were downloaded from the GEO (Gene Expression Omnibus) database and divided into PARP1\_H and PARP1\_L according to the front and rear thirds of the expression level of PARP-1. First, we systematically analyzed the influence of PARP-1 on DNA damage repair, prognosis, and chemoradiotherapy sensitization of glioma. Next, differentially expressed DNA-repair related genes (DEGs) were identified between PARP1\_H and PARP1\_L by LASSO (Least Absolute Shrinkage and Selection Operator) Cox analysis and applied to the construction of DPS. Based on the four-gene DPS, we then developed a new nomogram to assess overall survival in glioma patients. Additionally, a series of computer-aided techniques were applied for screening potential inhibitors for the DNA damage repair pathway. In conclusion, this study investigated the effect of PARP-1 on glioma prognosis and the sensitization effect of radiotherapy and chemotherapy, established a novel nomogram to evaluate the overall survival of glioma patients, and further explored targeted therapy for glioma.

## Methods and materials

### Gene expression datasets, data processing, and functional enrichment analysis

We acquired RNA-seq data of 639 glioma samples from the GEO (Gene Expression Omnibus) database. The survival data were obtained for all patients. According to the front and rear thirds of the expression level of PARP-1, the patients were divided into PARP1\_H ( $n = 213$ ) and PARP1\_L ( $n = 213$ ). Additionally, the RNA transcriptome analysis was carried out by transformation of log<sub>2</sub>-based FPKM values.

A total of 329 genes of DNA-repair proteins were downloaded from the PathCards website (<https://pathcards.genecards.org/>). To analyze signalling pathway enrichment, 278 genes of these genes detected in glioma patients were uploaded to Metascape (<https://metascape.org/>) to identify GO (Gene Ontology) Terms and KEGG (Kyoto Encyclopedia of Genes and Genomes) pathways

(Zhou et al., 2019). Terms were thought significant when the conditions of  $p < 0.01$  and the number of enriched genes  $\geq 3$  were met and grouped separately according to their membership similarity. And the term with the best  $p$ -value in every 20 clusters was selected.

## Prognosis and gene enrichment between PARP1\_H and PARP1\_L

We systematically analyzed the influence of PARP-1 on DNA damage repair, prognosis, and chemoradiotherapy sensitization of glioma. The OS (overall survival) of glioma patients was compared between PARP1\_H and PARP1\_L, PARP1\_H and PARP1\_L with chemotherapy, PARP1\_H and PARP1\_L with radiotherapy, and PARP1\_H and PARP1\_L with both chemotherapy and radiotherapy. Kaplan-Meier curves were drawn to show differences in survival time. The log-rank test was carried out to evaluate the significance of differences in survival times with a threshold of  $p < 0.05$ . In addition, expression levels of the 278 genes of the DNA-repair proteins were compared between PARP1\_H and PARP1\_L.

## Differential expression analysis

Differential expression analysis was calculated and carried out on RStudio by the Wilcoxon Rank Sum and Signed Rank Tests between PARP1\_H and PARP1\_L (Servant et al., 2010). The limma package of RStudio software was applied to distinguish the differentially expressed DNA-repair related genes (DEGs) between PARP1\_H and PARP1\_L. Genes with  $\log_2 |\text{fold change}| \geq 1$  and FDR (False Discovery Rate)  $< 0.05$  were chosen as DEGs (differentially expressed genes). Then, the ImmPort database identifies differentially expressed genes for DNA-repair proteins (DEGs) (<https://www.immport.org/>). Patients were divided into High ( $n = 213$ ) and Low ( $n = 213$ ) groups based on the median expression level of each DEG.

The OS of glioma patients was compared between the High and Low groups of each DEEG. Kaplan-Meier curves were drawn to show differences in survival time. The log-rank test was carried out to evaluate the significance of differences in survival times with a threshold of  $p < 0.05$ .

Construction of the PARP1-related DNA-repair prognostic signature (DPS).

To build the PARP1-related DNA-repair prognostic signature (DPS), DEGs were put in LASSO Cox regression and analyzed by the “glmnet” R package (Tibshirani, 1997) (Friedman et al., 2010). The DPS model was constructed from weighted Cox regression coefficients to estimate the risk score for each patient. Patients were classified as high or low risk according to the best cutoff values obtained by the “survminer” R package. We used the “survival ROC” R package to generate ROC (Receiver Operating Characteristic) curves (Heagerty et al.,

2000). And the area under the curve values of the ROC curve was calculated to assess the specificity and sensitivity of DPS.

## Development of the nomogram

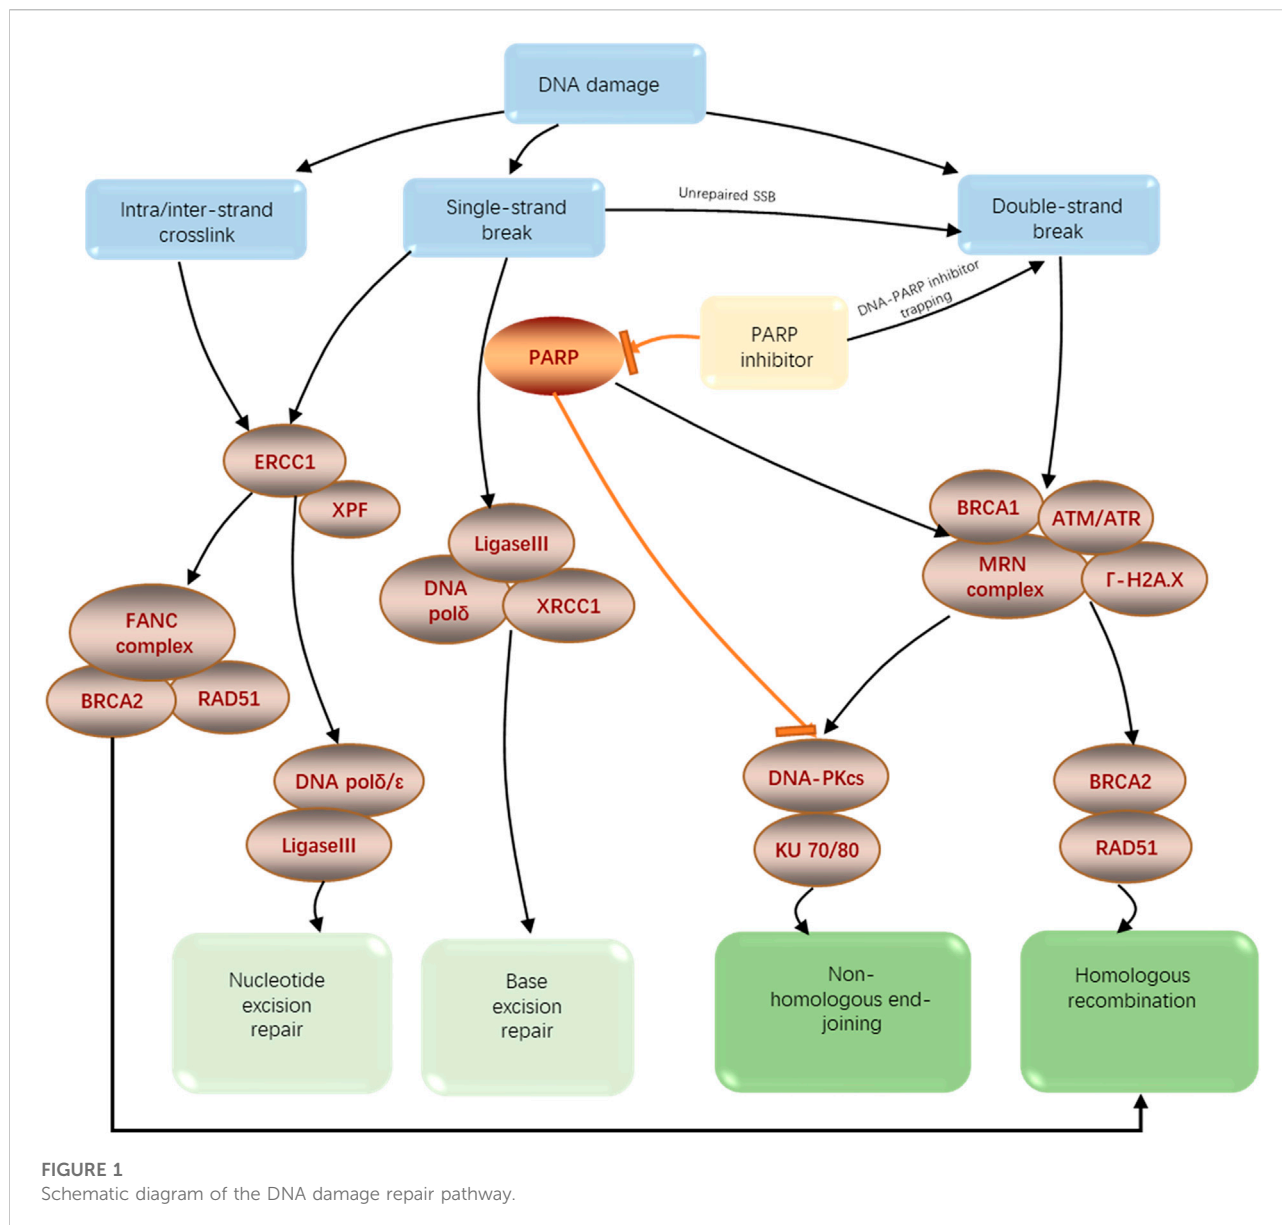

Univariate and multivariate Cox analyses were applied to assess the independent prognostic ability of DPS. Then we performed the “rms” package to construct an innovative nomogram according to the Cox analysis results. To determine the accuracy, calibration plots of observed vs. predicted probabilities of 1-, 3-, and 5-years OS were developed. The C-Index (Concordance Index) was calculated to determine the discriminative power of the model. And the C-index was corrected using bootstraps.

## Virtual screening of PARP-1 inhibitors using libdock, ADME and TOPKAT

DS 4.5 (Discovery Studio 4.5, Accelrys, Inc.) is a suite of software for modelling large and small-molecule systems. Libdock, ADME (absorption, distribution, metabolism, excretion), and TOPKAT (Toxicity Prediction by Computer Assisted Technology) modules of DS 4.5 were used for virtual screening firstly. Libdock is a rigid-based docking program. During this procedure, hotspots for PARP-1 were calculated, and the ligands formed favorable interactions based on the hotspots. Afterward, poses of all the ligands were ranked according to their Libdock scores. The 3.22 Å crystal structure of PARP-1 in complex with inhibitor (PJ34L) was downloaded from PDB (Protein Database) (<https://www.rcsb.org>). NAD + binds to PARP-1 and is catalyzed to ADP ribose in this region. So, the binding pocket was chosen as the docking region for screening. Moreover, 17,799 natural, named, and purchasable molecules were downloaded from the ZINC15 database for virtual screening (<https://zinc.docking.org/>). And Lynparza (also called Olaparib) was selected as a reference inhibitor (Brooks et al., 2009). Only the top 20 molecules were chosen for the ADME and TOPKAT analysis. The ADME module was applied for calculating the pharmacological properties of selected compounds and Lynparza, including the absorption, distribution, metabolism, and excretion. TOPKAT module was used to assess the toxicological properties. Finally, two molecules were chosen as favorable candidates based on the above results.

## Precise molecular docking using CDOCKER

Precise docking was performed between selected compounds, Lynparza, and prepared PARP-1 by CDOCKER module of DS 4.5 based on CHARMm36 force field. The receptor is held rigid while the ligands flex during the docking process. The CDOCKER interaction energy indicating ligand binding affinity was calculated for each complex pose. The binding site sphere of PARP-1 was

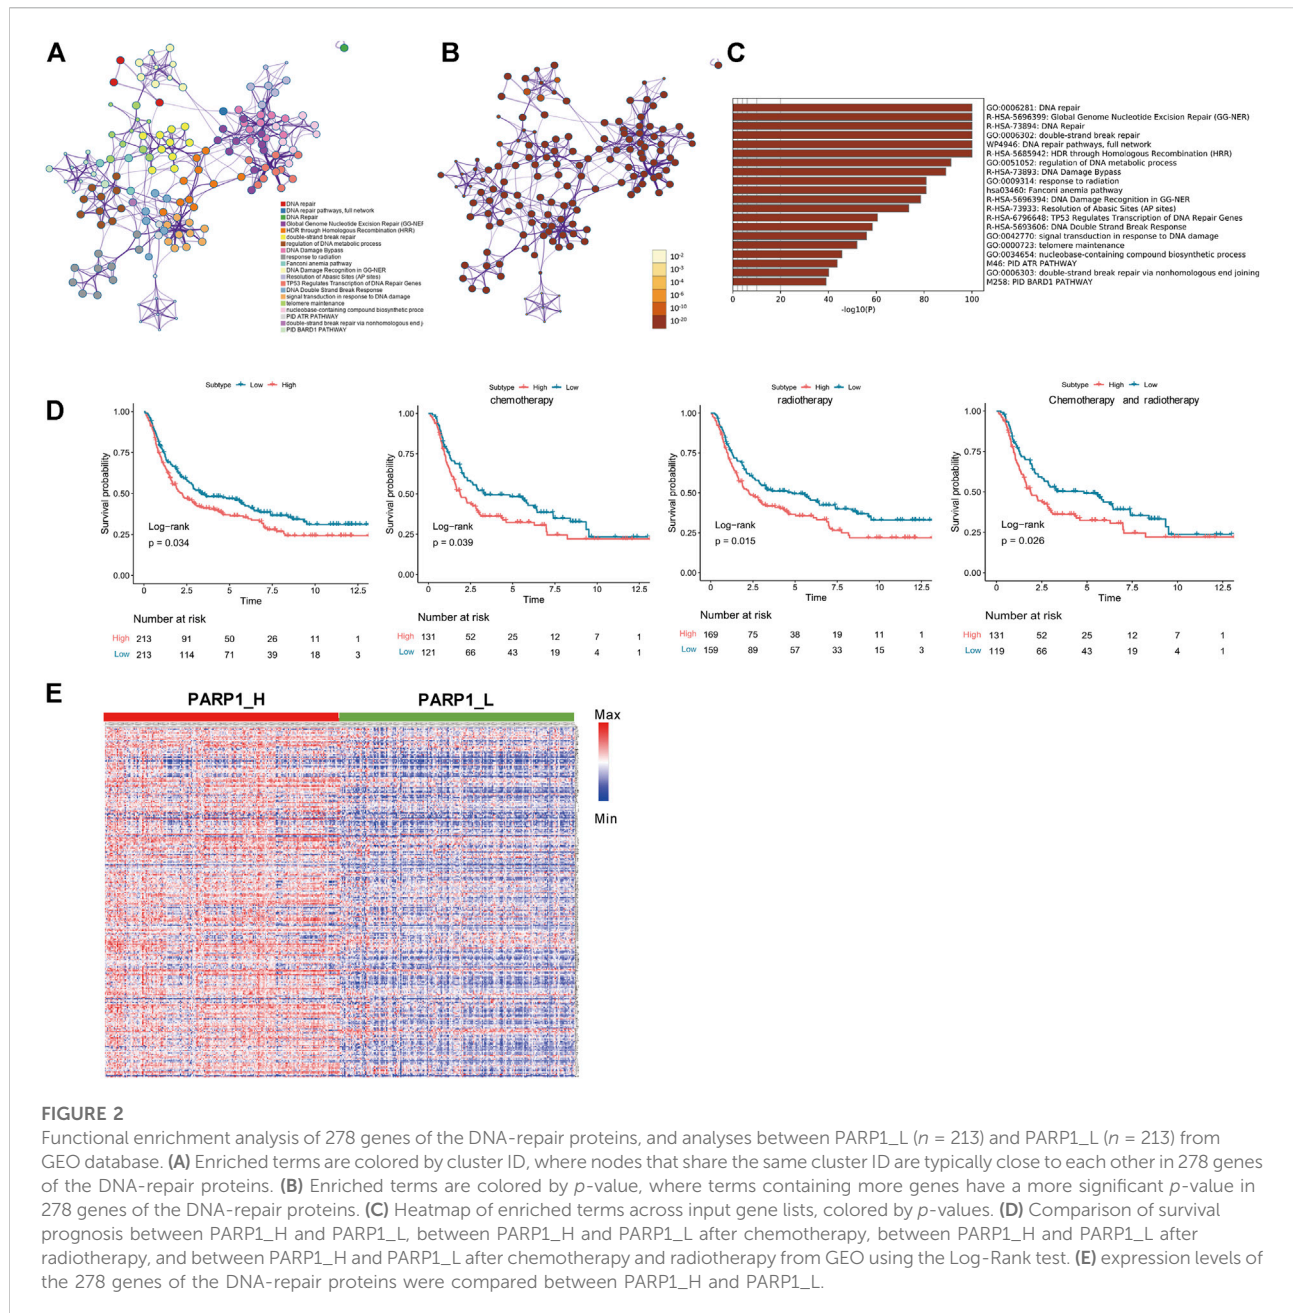

defined as the region within a radius of 13 Å from the geometric centroid of Lynparza. Ligands can bind to residues within the binding site sphere during the docking process. Different poses of each test molecule were generated, and their CDOCKER interaction energies were analyzed separately. Schrodinger and PyMol software were used to visualize further the optimal postural binding of selected compounds, Lynparza and PARP-1.

## Pharmacophore analysis and molecular dynamics simulation

Pharmacophores of selected compounds and Lynparza were analyzed by the 3D-QSAR module of DS 4.5. Only those with

energies below 10 kcal/mol can be retained, and a maximum of 255 conformations can be generated per molecule.

In addition, to assess the stability and affinity of each compound-PARP-1 complex in the natural environment, the best binding conformation was selected and prepared for Molecular dynamics simulation. The ligand- PARP-1 complex was placed in an orthorhombic box and solvated using an explicit periodic boundary solvation water model. To simulate the physiological environment of the system, sodium chloride was added. The production procedure was carried out for 100 ps and the time step was 2 fs. Concerning the initial complex setup, the trajectory protocol of DS 4.5 was performed to determine the trajectory for potential energy and RMSD (root-mean-square deviation).

## Result

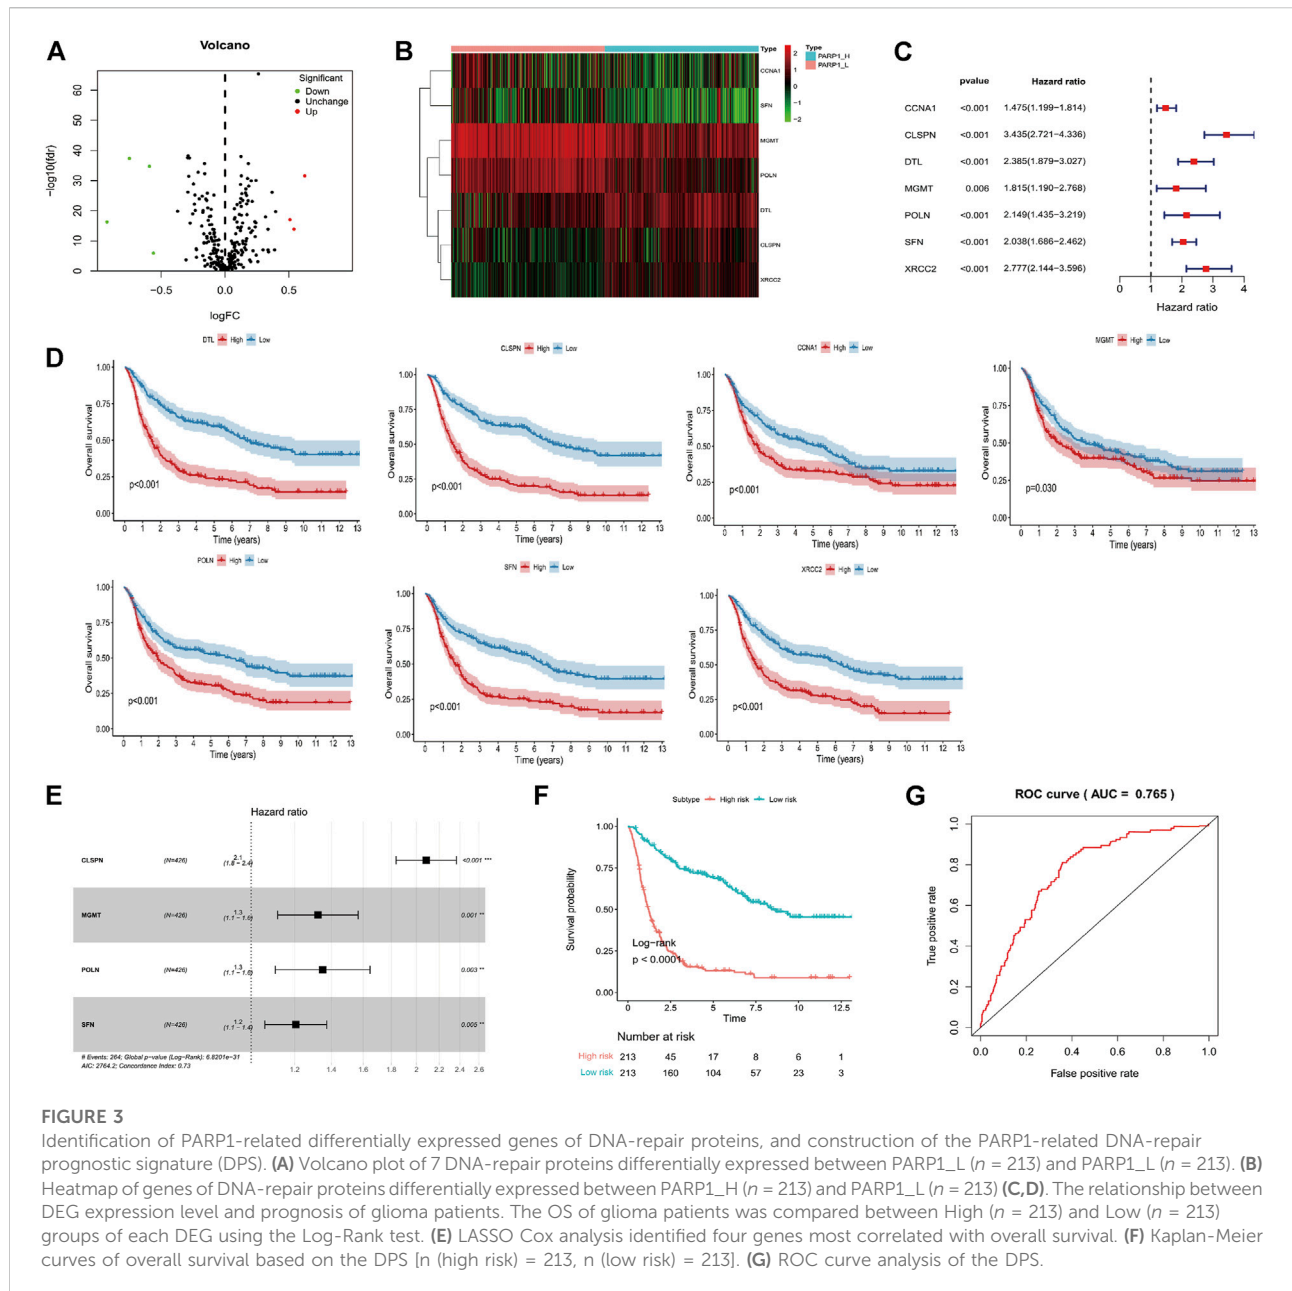

### Functional enrichment analysis

The 278 genes of the DNA-repair proteins were mainly enriched in GO:0006281: DNA repair, GO:0006302: double-strand break repair (GO terms), R-HSA-73894: DNA Repair, R-HSA-5685942: HDR through Homologous Recombination (HRR), R-HSA-5696399: Global Genome Nucleotide Excision Repair (GG-NER), WP4946: “DNA repair pathways, full network” (KEGG). Each node represents a collective term,

colored first by cluster ID and its  $p$ -value, separately (Figures 2A–C).

### Comparison of prognosis and gene expression between PARP1\_H and PARP1\_L

Survival analysis indicated that the clinical prognoses of PARP1\_H and PARP1\_L were different. All glioma patients, patients with radiotherapy, patients with chemotherapy, and patients with both

The OS of glioma patients was compared between High ( $n = 213$ ) and Low ( $n = 213$ ) groups of each DEG using the Log-Rank test. **(E)** LASSO Cox analysis identified four genes most correlated with overall survival. **(F)** Kaplan-Meier curves of overall survival based on the DPS [ $n$  (high risk) = 213,  $n$  (low risk) = 213]. **(G)** ROC curve analysis of the DPS.

radiotherapy and chemotherapy had a better prognosis in PARP1\_L than PARP1\_H (Log-Rank test,  $P$  (all) = 0.034;  $P$  (radiotherapy) = 0.015;  $P$  (chemotherapy) = 0.039;  $P$  (radiotherapy and chemotherapy) = 0.026) (Figure 2D). Additionally, as shown in Figure 2E, the expression levels of 278 DNA repair-related protein genes were significantly higher in PARP1\_H than in PARP1\_L.

Discrimination against differentially expressed DNA-repair related genes (DEGs).

Seven genes were confirmed according to the standard ( $\log_2$  |fold change|  $\geq 1$  and  $\text{FDR} < 0.05$ ), of which 3 genes were up-regulated, and four were down-regulated (Figure 3A).

Seven DEGs were chosen using the ImmPort database for performing prognostic analysis. Gene expression patterns are shown in Figure 3B. For each DEG, patients were divided into High ( $n = 213$ ) and Low ( $n = 213$ ) according to their median expression level. Then, the OS of glioma patients was compared between the High and Low groups of each DEG (Figure 3C). Patients of each DEG's High group had a worse prognosis than that of the Low group (Log-Rank test, CCNA1:  $p < 0.001$ , CLSPN:  $p < 0.001$ , DTL:  $p < 0.001$ , MGMT:  $p = 0.03$ , POLN:  $p < 0.001$ , SFN:  $p < 0.001$ , XRCC2:  $p < 0.001$ ) (Figure 3D).

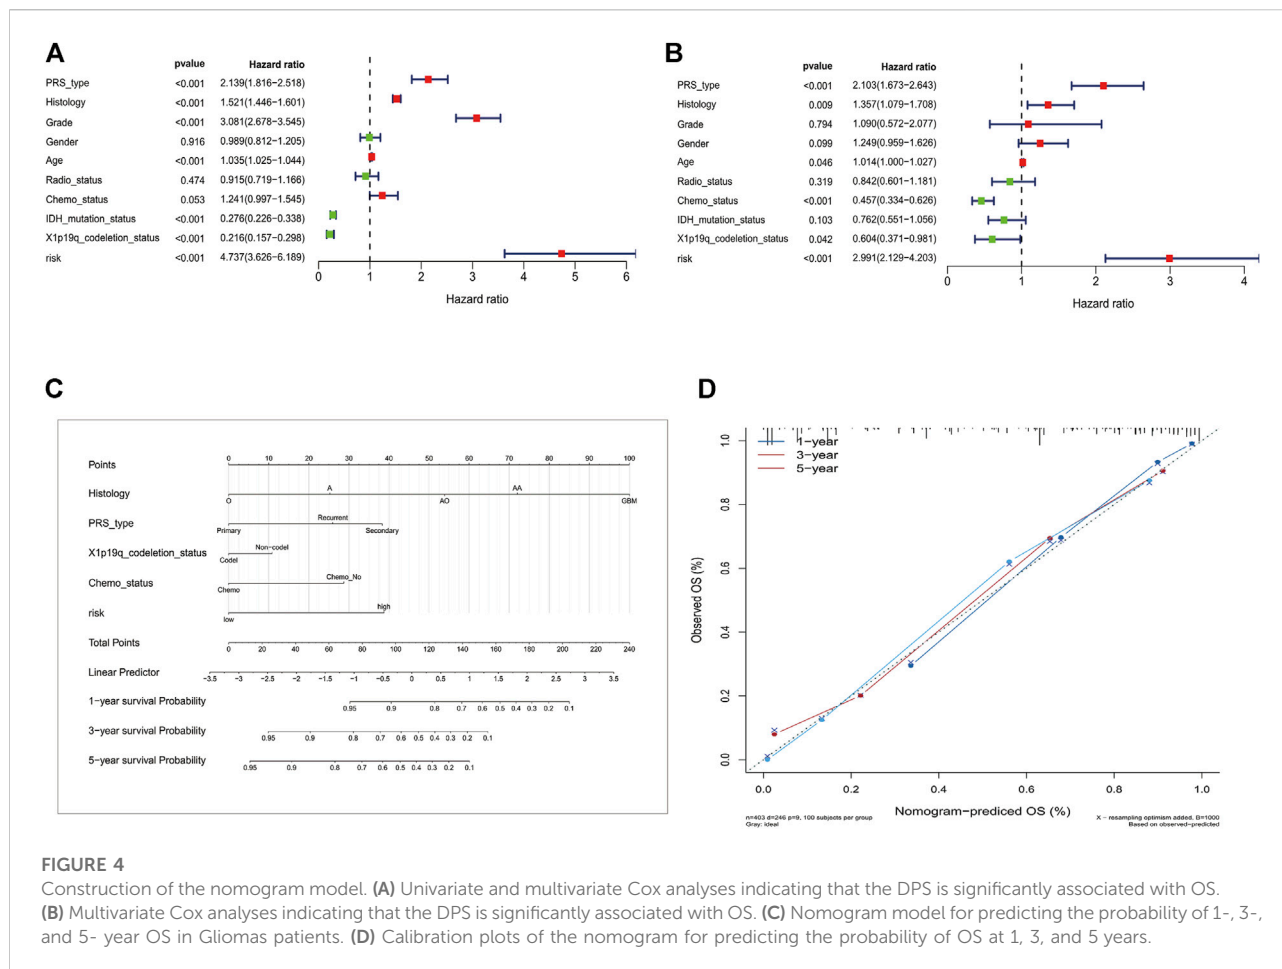

FIGURE 4

Construction of the nomogram model. (A) Univariate and multivariate Cox analyses indicating that the DPS is significantly associated with OS. (B) Multivariate Cox analyses indicating that the DPS is significantly associated with OS. (C) Nomogram model for predicting the probability of 1-, 3-, and 5-year OS in Gliomas patients. (D) Calibration plots of the nomogram for predicting the probability of OS at 1, 3, and 5 years.

## Construction of the PARP-1-related DNA-repair prognostic signature

LASSO Cox regression analysis of DEGs was used to construct a PARP1-related DNA-repair prognostic signature (DPS) (Figure 3E). Risk scores were evaluated for each glioma patient (risk score =  $CLSPN \times 0.734 + MGMT \times 0.28 + POLN \times 0.3 + SFN \times 0.187$ ). Patients were divided into low-risk and high-risk groups according to the optimal cutoff value (0.89005466) evaluated by the “survminer” R package. Kaplan-Meier analysis showed that patients with low-risk scores had better outcomes than those with high-risk scores (Figure 3F). The ROC curve analysis of the DPS suggested good prognostic ability for OS (Figure 3G).

## Establishment of a DPS-based nomogram model

The DPS was indicated to be significantly associated with OS (Hazard ratio: 4.737%, 95% confidence interval: 3.626–6.189,  $p < 0.001$ ) by the univariate Cox analysis (Figure 4A). From the multivariate Cox

analysis, DPS proved to be an independent prognostic factor (Hazard ratio: 2.739, 95% confidence interval: 1.923–3.902,  $p < 0.001$ ) (Figure 4B). Finally, a DPS-based nomogram model was established (Figure 4C). The C-index was 0.674, which revealed the specific discriminative ability of the nomogram model. Moreover, the observed vs predicted probabilities of 1-, 3-, and 5-years OS showed good agreement in the calibration plot (Figure 4D).

## Virtual screening using libdock, ADME, and TOPKAT of DS 4.5

Based on the above results, PARP-1 was proved an essential target for glioma therapy and prognosis. Therefore, we took PARP-1 as the target for further drug screening. The 3D (three-dimensional) structures of PARP-1 and the Lynparza-PARP1 complex are displayed in Figures 5A, B. According to Libdock’s results, 2,996 compounds were identified that stably bind to PARP-1. Among them, 37 molecules had higher Libdock scores than Lynparza (ranking: 38, Libdock score: 153.31). Table 1 lists the top 20 compounds by Libdock scores.

The pharmacological and toxicological properties of the top 20 compounds and Lynparza were evaluated by the ADME (Table 2) and TOPKAT (Table 3) modules of DS 4.5. Compounds 1 (ZINC000014951634) and 2 (ZINC000053057130) showed no hepatotoxicity, non-CYP2D6 inhibitor, low Ames mutagenicity, low rodent carcinogenicity, and low developmental toxicity potential, which strongly suggests their promising application in drug development. So, compounds 1 and 2 were chosen as favorable inhibitors of PARP-1. The 3D and two-dimensional (2D) chemical structures of compounds 1, 2 and Lynparza are shown in Figures 5C–E.

## Ligand binding analysis

Compounds 1, 2, and Lynparza were precisely docked into the function pocket of PARP-1 by the CDOCKER module (Figures 6, 7). Table 4 showed that the CDOCKER interaction energies of compounds 1, 2 were significantly lower than that of the reference ligand Lynparza (-54.2416 kcal/mol), indicating that these two compounds have higher stability and affinity with PARP-1 than Lynparza.

Structural analyses of the ligands-PARP-1 complex were also performed for the hydrogen bonds, Pi-Pi interaction, Pi-Alkyl interaction, Pi-Anion interaction, and Alkyl interactions (Figures 6, 7 and Table 5, 6). Results showed

TABLE 1 Top 20 ranked compounds with higher libdock scores than lynparza.

## Pharmacophore analysis and molecular dynamics simulation

According to the evaluation of feature pharmacophores by the 3D-QSAR module of DS 4.5, Compound 1 displayed eight hydrogen bond acceptors, ten hydrogen donors, four hydrophobic centres, and six aromatic rings, and one ionizable positive, respectively (Figure 8A). Compound 2 displayed seven hydrogen bond acceptors, nine hydrogen donors, four hydrophobic centres, four aromatic rings, and one ionizable positive, respectively (Figure 8B). In addition, Lynparza formed sixteen feature pharmacophores, including seven hydrogen bond acceptors, one hydrogen donor, four hydrophobic centres, and four rings aromatic respectively (Figure 8C).

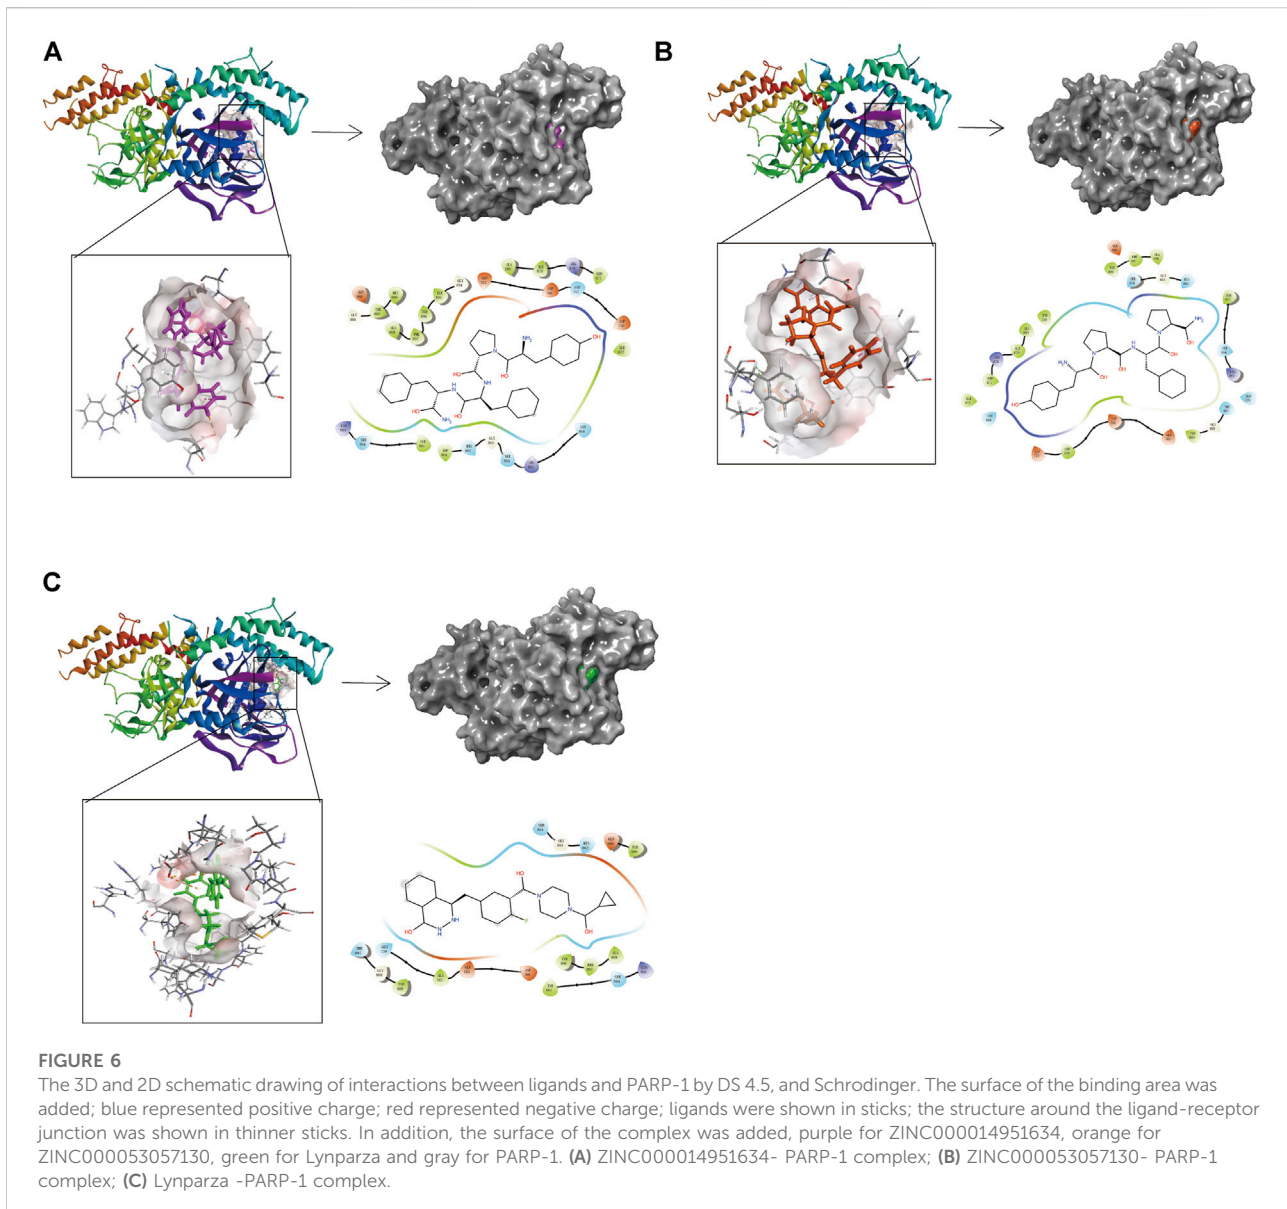

Additionally, the molecular dynamics simulation module was carried out to assess the stabilities of the ligand-PARP-1 complexes in the natural environment. These complexes' RMSD and potential energies were stable over time (Figures 8D, E). And the RMSD trajectory of each complex reached equilibrium after 70 ps. So, hydrogen bonds and Pi-related interactions formed by compounds with PARP-1 may contribute to the stability of these complexes. And their

complexes could exist in a natural environment stably as Lynparza.

## Discussion

Genomic instability is one of the most prevalent features of tumor cells, which offers therapeutic opportunities for glioma (Lord and Ashworth, 2012) (Hannigan et al., 2013). DNA damage repair (DDR) determines not only the occurrence and development of tumors but also the sensitivity or tolerance of tumor cells to radiotherapy, chemotherapy, and other treatments that induce DNA damage. PARP-1 was widely studied and played a key role in DNA repair pathways (Bryant et al., 2005; Brown et al., 2017). So, it is significant to explore PARP-1's role in the prognosis prediction of glioma patients and develop more effective treatments.

In this study, we first systematically analyzed the influence of PARP-1 on DNA damage repair, prognosis, and chemoradiotherapy sensitization of glioma. 278 genes of the DNA damage repair proteins were mainly enriched in

DNA repair, double-strand break repair, HDR through Homologous Recombination (HRR), Global Genome Nucleotide Excision Repair (GG-NER), 'DNA repair pathways, full network'. Additionally, the expression levels of 278 DNA repair-related protein genes were significantly higher in PARP1\_H than that in PARP1\_L, which proved that PARP-1 matters a lot in the DNA repair pathway. Furthermore, all glioma patients, patients with radiotherapy or chemotherapy, and patients with both radiotherapy and chemotherapy had a better prognosis in PARP1\_L than PARP1\_H. According to the theory of combined lethality, radiotherapy and chemotherapy cause DNA damage in tumor cells, combined with the inhibitory effect of PARP-1 on DNA repair, resulting in a more potent cytotoxic effect on tumor

cells (Shen et al., 2013). Therefore, PARP-1 is expected to be an evaluation indicator for the prognosis of patients. Inhibition of PARP-1 can improve the prognosis of glioma and promote chemoradiotherapy sensitization, which offers new ideas for treating glioma.

Next, we analyzed their DEGs between PARP1\_H and PARP1\_L. There were seven DEGs, including CCNA1, CLSPN, DTL, MGMT, POLN, SFN, and XRCC2. And the High group of each DEG had a worse OS than that of the Low group (Log-Rank test, CCNA1:  $p < 0.001$ , CLSPN:  $p < 0.001$ , DTL:  $p < 0.001$ , MGMT:  $p = 0.03$ , POLN:  $p < 0.001$ , SFN:  $p < 0.001$ , XRCC2:  $p < 0.001$ ). The abnormal methylation of the promoter of the CCNA1 gene is closely related to the occurrence, growth, invasion, and metastasis of malignant

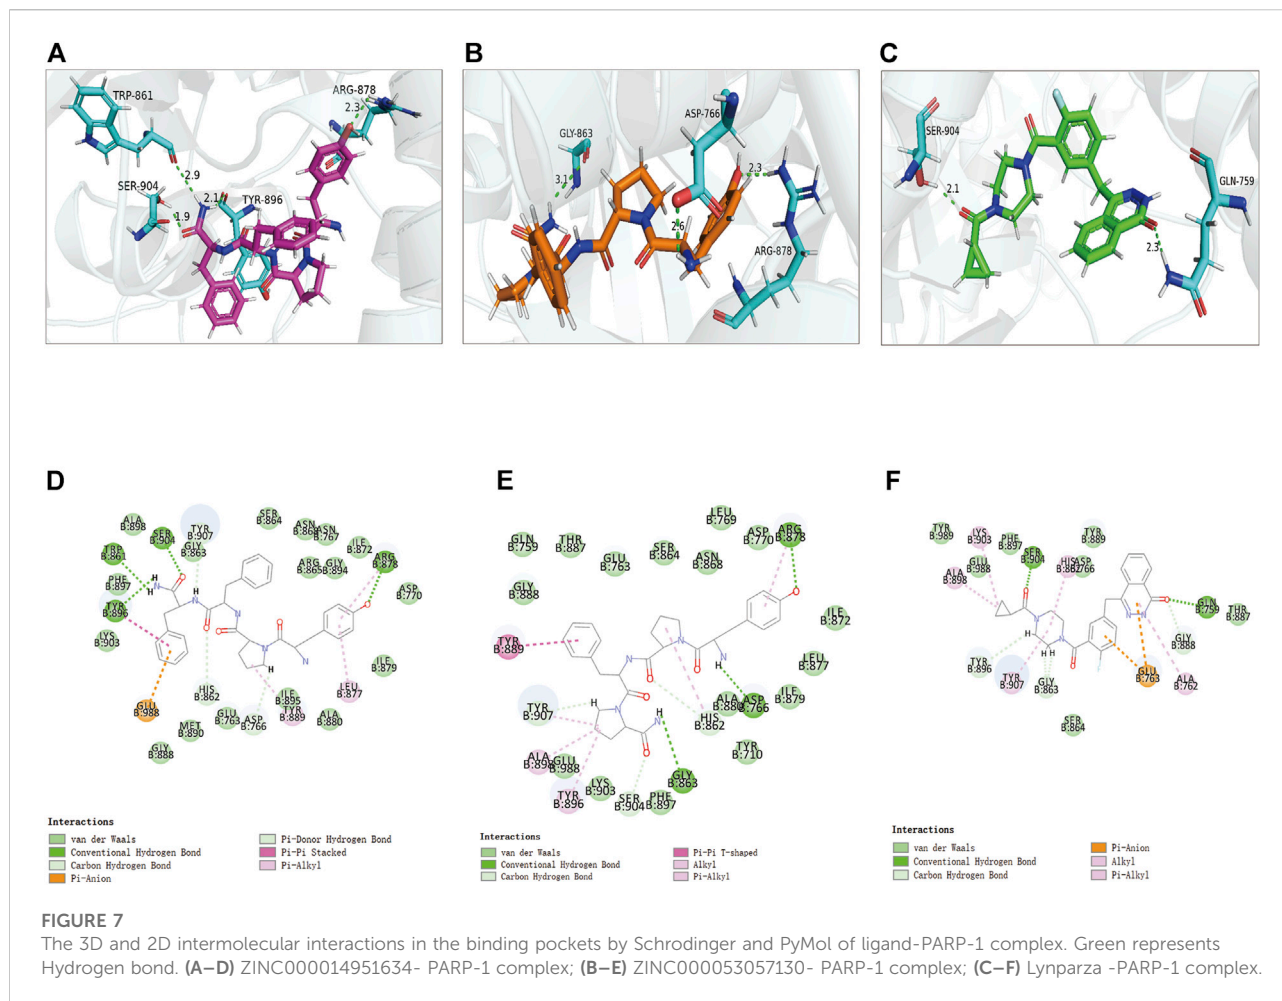

TABLE 4 | CDOCKER interaction energy of compounds with PARP-1.

Lynparza	-54.2416

tumors, such as cervical cancer (Yang et al., 2009). But it has not been reported in glioma. In addition, CLSPN regulates the cell G0/G1 phase cycle by the P53-p21/p27 molecular signaling pathway, thereby affecting the proliferation of glioblastoma. CLSPN may be a potential therapeutic target for glioblastoma. DTL is a protein predominantly expressed in the nucleus. It is a potential target for breast cancer, liver cancer, colorectal cancer, etc., but its role in glioma has not been reported (Baraniskin et al., 2012; Zhu et al., 2016; Li et al.,

2022). MGMT promoter methylation is essential to evaluate glioma patients' sensitization to alkylating agents for personalized and precise treatment and evaluate prognosis (Mansouri et al., 2019). POLN encodes a DNA polymerase type-A family member, which plays a role in DNA repair and homologous recombination. And it was first identified as a potential target for glioma. SFN (Stratifin), a cell cycle checkpoint protein, has been reported to be involved in tumorigenesis such as ovarian and nasopharyngeal cancer. Higher SFN expression was associated with significantly poorer overall survival (Hu et al., 2019; Zhang et al., 2019). XRCC2, a novel oncogene, is significantly overexpressed in glioma and can lead to poor prognosis in glioma patients (Liu et al., 2021). In summary, CCNA1, DTL, and SFN could serve as a new biomarker for glioma diagnosis, treatment, and prognosis evaluation.

Subsequently, a PARP1-related DPS was developed. CLSPN, MGMT, POLN, and SFN were identified as hub genes in our DPS by LASSO Cox regression. Furthermore, univariate and multivariate Cox analyses demonstrated that

the four-gene DPS was an independent prognostic factor. Moreover, a predicting nomogram was constructed based on the PARP1-related DPS with an AUC value of 0.765 for predicting 1, 3, and 5-years patient survival.

Additionally, PARP-1 was proved an effective target for glioma therapy. So, a series of computer-aided techniques, including Discovery Studio 4.5, Schrodinger, and PyMol, were applied for virtual screening of favorable PARP-1 inhibitors. Lynparza was chosen as a reference inhibitor. Firstly, Libdock was performed between ligands and PARP-1 for virtual screening. Compounds with higher Libdock scores show better energy optimization and more stable conformations

than others. The top 20 compounds by Libdock scores were chosen for subsequent pharmacological and toxicological analysis. Finally, ZINC000014951634 and ZINC000053057130 were shown to be no hepatotoxicity, non-CYP2D6 inhibitor, low Ames mutagenicity, low rodent carcinogenicity, and low developmental toxicity potential, which also strongly suggests their perspective application in drug development.

Additionally, to further evaluate ligand-protein complex affinity and stability, Molecular dynamics simulation and precise docking by CDOCKER were performed. Table 4 showed that the CDOCKER interaction energies of

compounds 1 and 2 were significantly lower than that of the reference ligand Lynparza ( $-54.2416$  kcal/mol), which indicated that these two compounds had higher stability and affinity with PARP-1 compared to Lynparza. Moreover, compound 1 and compound 2 formed several hydrogen bonds and Pi-related interactions as Lynparza. Furthermore, compounds 1, 2, and Lynparza interacted with PARP-1 by amino acid residues 861–988. The active position of the binding pocket provided a guide for PARP-1 targeted drug research and deep learning for PARP-1's structure. In addition, compounds 1 and 2 were shown to have multiple pharmacophores, again suggesting the potential of compounds 1 and 2 as drugs. Moreover, according to the molecular dynamics simulation's results, both potential energy and RMSD of these two complexes stabilized with time, validating the stabilities of the ligand-PARP-1 complexes in the natural environment.

Last but not least, this study provided new insight into the treatment and prognosis of glioma. Although this study was well designed and accurately measured, we acknowledge

that this study still has some limitations. More prospective studies are needed to validate our results. And drugs need clinical trials to validate the specificity of PARP-1 inhibition.

## Conclusion

In this study, PARP-1 was proved to be an evaluation indicator for the prognosis of patients. And inhibition of PARP-1 can improve the prognosis of glioma and promote chemoradiotherapy sensitization, which offers new ideas for treating glioma. Furthermore, we developed a novel nomogram to quantitatively predict patient survival based on PARP-1-related DPS. And CCNA1, DTL, and SFN were discovered as novel biomarkers for glioma diagnosis, treatment, and prognosis evaluation. PARP-1 was proved an effective target for glioma therapy based on the results above. So, a series of computer-aided techniques were applied for screening favorable PARP-1 inhibitors.

ZINC000014951634) and compound 2 (ZINC000053057130) were selected as favorable inhibitors of PARP-1. In conclusion, this study provided new insight into the treatment and prognosis of glioma.

## Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary Material.

## Author contributions

This study was completed with teamwork. Every author has made substantial contributions to the study. SZ and QY have come up with the conception. Additionally, HL did the design of the work. YH was responsible for the creation of new software used in work. ZW has drafted the work. JX and ZH completed the data collection part. Furthermore, an analysis of the data was done by HL. As for the interpretation of the data, ZD has contributed a lot to this part. SZ and QY substantively revised it.
