Floods have been the subject of repeated alarming news in 2021, for their recurrence has increased in frequency all over the world with very high-cost consequences in terms of economic losses and human suffering. Floods represent one of the most common and severe natural disasters, capable of disrupting people's livelihoods around the world. Their effects are particularly evident in low-income countries, where the lack of adequate infrastructure, limited know-how and the scarcity of monitoring systems, make the situation even more serious.

Rentschler and Salhab (2020) in their recent study of 189 countries' exposure to floods and poverty, find that 19% of the world's population is in conditions of direct exposure to risk during flood events that occur once every 100 years. Of this percentage, the majority of the population at risk is concentrated in developing countries, most located in sub-Saharan Africa and in South and East Asia. The number of people exposed to flood risk has increased enormously in recent decades, surpassing, already in 2020, the estimates made for 2050 (Jongman et al., 2012; Rentschler and Salhab, 2020). This situation is due to various factors, among which climate change plays a fundamental role. Emanuel (2013) estimates that the frequency of tropical cyclones is increasing by 10–40% during the first three quarters of the twenty-first century, while their intensity is estimated at an increase of about 15% as calculated by Hong et al. (2021). However, it is not only major and infrequent floods that pose a danger to exposed populations, even less rare and minor events can jeopardize particularly vulnerable populations (Hoeppe, 2016). The increase in susceptibility to flooding is also determined by the increase in population and urbanization of high-risk areas. The uncontrolled urbanization determines a change in land use which causes a direct influence on the increase in surface runoff levels (Huang et al., 2014; Liu et al., 2019).

In the light of these evidence, this Research Topic wanted to emphasize the importance of local strategies in managing flood risk, in order to increase public awareness and preparedness.

Scaini et al. focus attention on the importance of citizen involvement in flood risk management plans. Their participation in the development of local inputs for the measures to be taken to deal with the risk of flooding is still very limited, given the difficulty of quantifying the perceived risk because it is based on personal opinions. However, authors point out that perceived risks may correspond to evidence-based data and in their work, they present a project questionnaire which aims to characterize the perception of flood risk and its spatial distribution at the basin scale. The proposal was tested on the Tagliamento river, in Italy, one of the last free-flowing rivers in Western Europe and the last free-flowing Alpine river. The questionnaire was tested for assess risk perception and compare it to available hazard/risk maps. Results show that perceived risk is in good agreement with existing hazard and risk assessments. Furthermore, the population has shown a strong interest in being involved in handling the risk debate, expressing the belief that risk reduction is compatible with river conservation and both of these objectives should be achieved together.

The concepts of conservation of natural areas and a participatory approach in support of decision makers are also developed by Scricciu et al. who analyze the potential of nature-based solutions (NBS) to deal with the risk of flooding. The authors start from the basic hypothesis that the barriers posed to the wide diffusion of NBS are mainly due to the lack of involvement and knowledge integration of stakeholders during the design phases of NBS. For this reason, they propose a combined approach based on the integration of Fuzzy Cognitive Maps (FCM), Hydraulic Modeling (HM), and participatory Bayesian Belief Networks (BBN) aiming to facilitate the stakeholders' engagement and the knowledge integration process in NBS design and assessment. The proposal has been applied to the Lower Danube demo site, with the aim also of supporting the process of the Potelu Wetland restoration. The proposed methodology aims to demonstrate the suitability of the BBN, in support of FCM and HM, to evaluate the effectiveness of NBS in addressing

the risk of floods. The methodology presented can be applied in other areas and represents a useful tool for establishing the active involvement of stakeholders in the evaluation and implementation of NBS.

Finally, Mokkenstorm et al. present a methodology for flood detection based on the use of Passive Microwave Remote Sensing (PMRS). The authors stress the importance of the application of remote sensing satellite data, particularly in ungauged river basins of developing countries, due to their low cost and low maintenance. Particularly, this study focuses on determining whether PMRS images can actually be used for the prevention of damage caused by floods and the cases of application are two small-scale basins in Malawi. Two indices were analyzed: the *m* index, expressed as the magnitude relative to the average flow, and an index that takes into account an additional wet calibration cell. Results, compared with the discharge estimates of the Global Flood Awareness System, show that the detected flood levels are very accurate, demonstrating that the methodology is valid and particularly useful for monitoring rivers of data-scarce areas.

In summary, this *Research Topic* wants to draw attention to two points of reflection: 1) The need to involve stakeholders at all levels in the planning of actions aimed at reducing the risks associated with floods is preponderant, given the considerable increase in urban settlements in high-risk areas of developing countries. 2) Likewise, we hope that new lines of research will open up to explore innovative solutions that help in risk management without having to resort to costly methods, which involve manpower or require continuous maintenance.

AUTHOR CONTRIBUTIONS

The authors are co-editors which organized this Research Topic, substantially, directly, and intellectually contributed to the work on this Research Topic and the manuscript and approved it for publication. All authors contributed to the article and approved the submitted version.
