Objectives: An increased number of elderly individuals affected by rheumatoid arthritis (RA) has been reported, including both patients with RA onset in advanced age and patients aged with the disease. In this registry-based study, we aimed to analyze the retention rate and cause of discontinuation of biologic (b) and targeted synthetic (ts)-disease-modifying anti-rheumatic drugs (DMARDs) in RA patients over 65 year old.

Methods: RA patients enrolled in the Italian GISEA registry and starting a b- or a ts-DMARD over 65 years of age were included. Demographic, clinical, serologic, and therapeutic features were collected.

Results: A total of 1,221 elderly RA patients were analyzed (mean age 71.6 ± 5.2 years). RA was diagnosed before 65 years in 72.5% of cases, a 60.6% of patients experienced a previous b- or ts-DMARD. In patients older than 65 initiating a new b- or ts-DMARDs, tumor necrosis factor alpha inhibitors (TNFi) were prescribed in 29.6% of patients, abatacept in 24.8%, anti-interleukin 6 receptor antagonists (anti-IL6R) in 16.3%, Janus kinases inhibitors (JAKi) in 24.9%, and rituximab in 4.4%. The main causes of discontinuation were primary or secondary inadequate responses (66.1%). The median retention rate for all treatments was 181.3 weeks. A statistically higher retention rate was observed

for abatacept when compared to TNFi ($p = 0.02$), JAKi ($p < 0.001$), and anti-IL6R ($p < 0.001$), and for TNFi vs. JAKi ($p = 0.013$).

Conclusion: We described, in a real-life setting, elderly RA patients treated with a biologic or a ts-DMARD in Italy. Loss of efficacy was the main cause of discontinuation, and the DMARD safety profile suggests that age does not contraindicate their use. Our study reinforced that the control of disease activity is mandatory.

KEYWORDS

rheumatoid arthritis, elderly, comorbidities, treatment, retention rate, safety

Highlights

- Loss of efficacy is the main cause of drug discontinuation in elderly rheumatoid arthritis patients.
- Comorbidities and disease activity are associated with drug discontinuation in elderly rheumatoid arthritis patients.
- In elderly RA patients, abatacept and TNF-alpha inhibitors are associated with a better retention rate.

Introduction

Over the past years, an increased number of elderly individuals affected by rheumatoid arthritis (RA) has been observed (1, 2). In this group, both patients with RA onset at an advanced age and patients with an early occurrence of RA aged with the disease were included.

The increased age of the RA population can be attributed primarily to the improved management of the disease and associated conditions, as well as the overall increase in life expectancy (3, 4).

Among elderly RA patients, those with late-onset disease are described as experiencing more severe joint involvement and systemic symptoms; however, existing literature indicates that rheumatologists tend to adopt a less aggressive treatment approach in elderly patients (5). In this population, rheumatologists often postpone the use of biologic drugs, instead opting for prolonged use of steroids or non-steroidal anti-inflammatory drugs (NSAIDs) and employing a less intensive “treat to target” strategy (5).

Several factors contribute to the complexity of treating RA in elderly patients, such as the presence of other medical conditions, the use of multiple medications (polytherapy), extra-articular manifestations of RA, and the aging of the immune system (immunosenescence), which can lead to increased frailty (1).

Currently, treatment guidelines do not take into account the age or comorbidities of RA patients, and clinical trials typically focus more on younger individuals with RA (6).

The “Gruppo Italiano per lo Studio della Early Arthritis” (Italian Group for the Study of Early Arthritis; GISEA) includes 21 hospital and community-based rheumatology units throughout Italy. It has developed and maintained a nationwide registry to promote the study of patients with inflammatory arthritis according to standard-of-care criteria (7, 8).

The main objective of this study was to analyze the rheumatologists’ preferences in the prescription of biologic (b-) and targeted synthetic (ts)-disease-modifying anti-rheumatic drugs (DMARDs) in RA patients aged at least 65 years. Additionally, our

study aimed to investigate the retention rate and the cause of discontinuation of biologics and ts-DMARDs in the elderly RA population enrolled in the GISEA registry.

Patients and methods

Among subjects included in the GISEA registry, patients were enrolled in the study when a biologic (b- or ts-DMARD) was started over 65 years of age in a period between 1 January 2019 and 31 December 2021, independently from previous therapies with b- or ts-DMARDs. For patients treated with more b- or ts-DMARDs prescribed after 65 years of age, only the first was evaluated.

The GISEA registry enrolled patients classified as affected by RA according to the 1987 or 2010 American College of Rheumatology (ACR) criteria (2). Data evaluated for the study included age, gender, disease duration, use of oral corticosteroids (CSs), and conventional DMARDs (namely, methotrexate, leflunomide, sulphasalazine, and hydroxychloroquine), body mass index (BMI), presence and number of comorbidities, presence and number of extra-articular RA manifestations, 28-joint Disease Activity Score (DAS28) and clinical disease activity index (CDAI), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), anti-citrullinated peptide antibodies (ACPAs), and rheumatoid factor (RF). Comorbidities recorded included anemia, anxiety/depression, cardiovascular diseases (coronary artery diseases, chronic heart failure, and arrhythmias), arterial hypertension, cerebrovascular diseases, liver diseases, acute and chronic kidney diseases, peripheral vasculopathy, diabetes, chronic obstructive pulmonary diseases, osteoporosis, thyroid dysfunction, and cancer. RA-related extra-articular manifestations (rheumatoid nodules, interstitial lung disease, Sicca syndrome, and vasculitis) were also collected. Causes of drug discontinuation (inadequate response, side effects, remission, or other) were recorded. We defined inadequate response as failure in the achievement of a remission or a low disease activity according to EULAR recommendations (9). A secondary inadequate response was defined as a failure of the treatment after a first

good response (9). Patients with more than 15% of the missing data were excluded from the analysis. The study was approved by the local ethical committee of “Area Vasta Emilia Nord,” and each patient gave their consent.

Statistical analysis

Continuous variables have been reported as mean \pm standard deviation, median and interquartile (IQR) range, and categorical variables were reported as absolute numbers or percentages. Differences among patients who discontinued or continued treatment were analyzed using the Mann–Whitney test for non-parametric variables, and chi-square or Fisher tests, when appropriate, were used for categorical variables. Global persistence in therapy and the 2-year retention rate were evaluated by the mean of Cox regression. Then, a multivariate analysis was performed to analyze the effect of features at baseline on patients with regard to drug discontinuation (10). Analyses were performed using the STATA14 software (StataCorp LLC, College Station, TX, USA), with a value of $p \leq 0.05$ considered to be statistically significant.

Results

We analyzed data from 1,221 elderly patients affected by RA; the female-to-male ratio was 3.79, and the mean age was 71.6 ± 5.2 years (23.7% of patients were older than 75); 55.3% of patients were positive for

both RF and ACPA, while 77.8% of patients showed at least one of them. RA was diagnosed before 65 years in 72.5% of patients, while the diagnosis was performed over 65 years in 27.5% of patients. The mean disease duration was 14.6 ± 10.4 years. Comorbidities were detected in 55.6% of the population. A previous treatment with one or more b-DMARDs was discontinued in 60.6% of patients.

The demographic, clinical, and serological features of the patients enrolled are detailed in Table 1.

Among patients enrolled, the first b- or ts-DMARDs prescribed over 65 years of age were a tumor necrosis factor-alpha inhibitor (TNFi) in 362 (29.6%) patients, and abatacept (CTLA4-Ig) in 303 (24.8%); 199 patients (16.3%) used anti-interleukin 6 receptor antagonists (anti-IL6R); Janus kinase inhibitors (JAKi) were the therapy chosen for 304 patients (24.9%), while rituximab (RTX) was prescribed in 53 patients (4.4%). Among the specific drugs, abatacept was the most prescribed drug (303 patients, 24.8% of the prescriptions), followed by baricitinib (198, 16.2%) and etanercept (186, 15.2%) (Table 2). The b- or ts-DMARD was prescribed as first-line after MTX in 39.4% of cases.

Data about age, sex, combination therapy with conventional synthetic DMARDs (csDMARDs), and GC for each biologic or ts-DMARDs class are summarized in Table 2.

On average, patients had 1.35 ± 1.6 comorbidities each. Comorbidities were 1.6 ± 1.9 for patients treated with RTX, 1.5 ± 1.6 for CTLA4-Ig, 1.4 ± 1.7 for anti-IL6, 1.3 ± 1.5 for TNFi, and 1.2 ± 1.5 for JAKi, respectively.

Median drug persistence

During a median follow-up of 61 weeks (IQR 26.4–104), 409 (33.5%) patients discontinued their treatment, 117 (38.5%) with JAKi, 115 (31.8%) with TNFi, 81 with both anti-IL6R (40.7%), 76 with CTLA4-Ig (25.1%), and 20 (37.7%) with RTX.

The median retention rate for all treatments was 181.3 weeks (CI 95% 157.7–204.9). In details, median retention rates for each class of drugs were: 254.1 weeks for CTLA4-Ig (CI 95% 219.4–288.9), 220.7 for RTX (CI 95% 104.2–337.2), 184 for TNFi (CI 95% 151.1–216.8), 136 for anti-IL6R (CI 95% 105.1–166.9), and 139.1 for JAKi (CI 95% 114.7–163.6). A statistically higher retention rate was observed at Mantel–Cox analysis for CTLA4-Ig when compared to TNFi ($p = 0.02$), JAKi ($p < 0.001$), and anti-IL6R ($p < 0.001$), and for TNFi vs. JAKi ($p = 0.013$) (Figure 1).

At 2 years, the cumulative retention rate from the beginning of the treatment was $54.9\% \pm 3.7$; in particular, the 2-year retention rate was $66.3\% \pm 3.8$ for CTLA4-Ig, $59.7\% \pm 8.8$ for anti-CD20, $54.9\% \pm 3.7$ for TNFi, $49.2\% \pm 0.5$ for anti-IL6R, and $52.7\% \pm 3.7$ for JAKi.

Predictive factors of discontinuation of all treatments

At univariate analysis, comorbidities, male sex, high disease activity (calculated with DAS28 and CDAI), a low BMI, and the second or third line of b- or ts-DMARDs therapy were associated with drug discontinuation. No differences were observed after stratification according to age at diagnosis. A combination therapy with MTX or other DMARDs reduced the risk of drug discontinuation. Among classes of b- or ts-DMARDs, treatment with JAKi or anti-IL6R drugs was associated with reduced persistence in therapy. On the contrary,

TABLE 1 Demographic, clinical, and serological features of 1,221 elderly rheumatoid arthritis patients enrolled in the study.

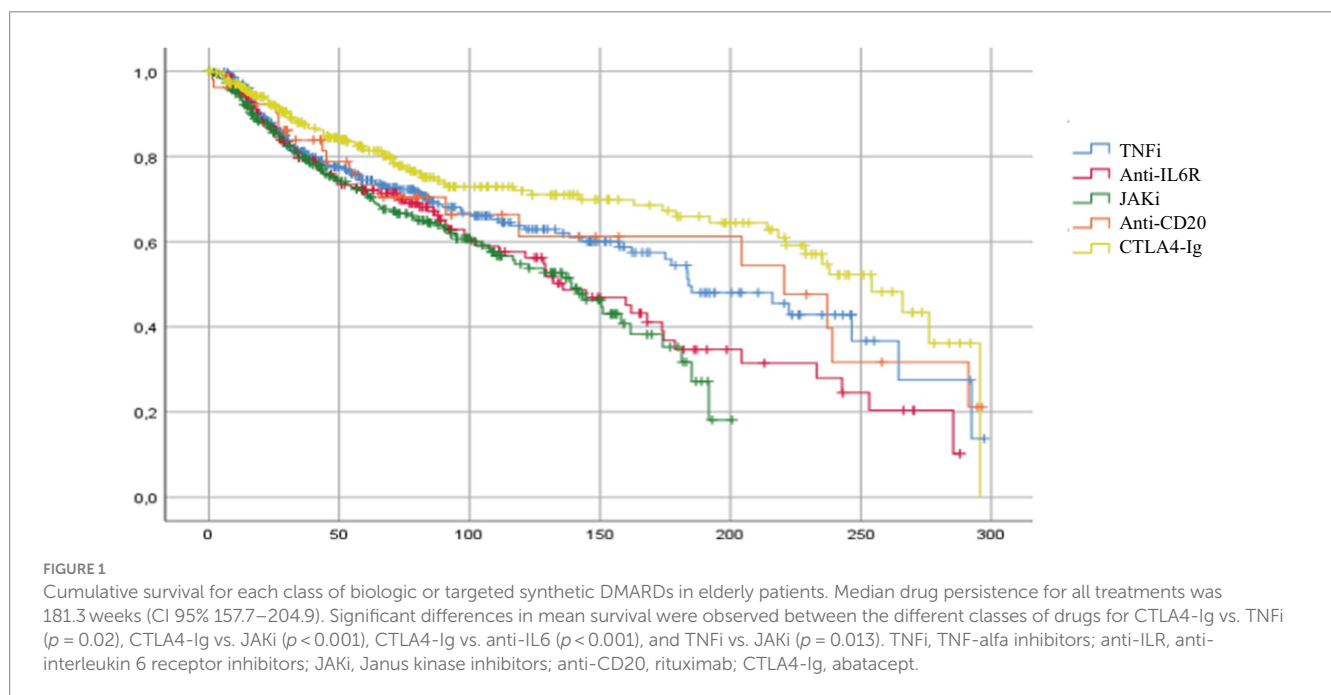

Patients enrolled	1,221
Females/Males (number)	966/255

DMARDs, disease-modifying anti-rheumatic drugs; anti-IL6R, anti-interleukin 6 receptor.

CTLA4-Ig was associated with a lower risk of drug discontinuation (Table 3).

CDAI (HR 1.022, CI95% 1.012–1.032, $p < 0.001$) and comorbidities (HR 1.331, CI95% 1.035–1.711, $p = 0.026$) were independently associated with drug discontinuation, while CTLA4-Ig (HR 0.683, CI95% 0.477–0.977, $p = 0.037$) was associated with a longer persistence in therapy in a Cox multivariate analysis model, including CDAI, sex, CTLA4-Ig, therapy with anti-IL6R or JAKi, combination therapy with a csDMARD, comorbidities, and line of b- or ts-DMARDs.

Predictive factors of discontinuation of treatment for each class of drugs

For each class of drugs, univariate analysis was performed to evaluate possible predictive factors for discontinuation. No findings were associated with an increased discontinuation rate for anti-IL6R, while multivariate analysis showed a RA diagnosis over 65 years as independent factors associated with discontinuation for JAKi, the number of comorbidities for RTX, and a high CDAI for TNFi. For CTLA4-Ig, a BMI < 20, older age, and a non-first line of treatment

were associated with increased drug discontinuation. Combination therapies with glucocorticoids or csDMARDs did not significantly change the retention rates of ts- and b-DMARDs (Table 4).

Causes of discontinuation of biologic/synthetic drugs

Among the 1,221 patients evaluated, 33.5% discontinued treatment. Discontinuation was observed in 31.5% of patients treated with TNFi, 40.7% of patients treated with anti-IL6R, 38.5% of patients treated with JAKi, 37.7% of patients with anti-CD20, and 25.1% of patients treated with CTLA4-Ig. Considering the entire population, the main causes of discontinuation were adverse events (18.1%), primary or secondary inadequate responses (17.1 and 49.3%, respectively), and others (15.4%). The main causes of discontinuation for each class of drugs are summarized in Figure 2.

Discussion

In the last few years, the number of RA patients older than 65 has significantly increased, accounting for more than 30% of the RA population (1, 3, 5, 7). This observation refers to both patients with RA onset at an advanced age, and patients with an early occurrence of the disease. Elderly onset RA is generally associated with a more balanced gender distribution, a higher frequency of acute onset, and more frequent involvement of large joints, sometimes complicating

differential diagnosis with polymyalgia rheumatica (11, 12). Although a more aggressive evolution of RA has been described in elderly patients, existing data reveal that conventional and biologic DMARDs are under-used in elderly RA patients (1, 5, 13).

Since elderly patients are frequently excluded from clinical trials, evidence-based data are scarce to develop guidelines for this population (6). For this reason, the pathophysiological aspects of aging and their implications in the treatment of RA in older patients need to be further investigated, as these aspects not only influence the clinical manifestations of RA onset but also impact the therapeutic options that can be proposed in this category of patients (1, 3, 4, 6, 14).

The large number of subjects included in the GISEA registry allowed us to describe, in a real-life setting, the features of elderly RA patients in Italy treated with a biologic or a ts-DMARD.

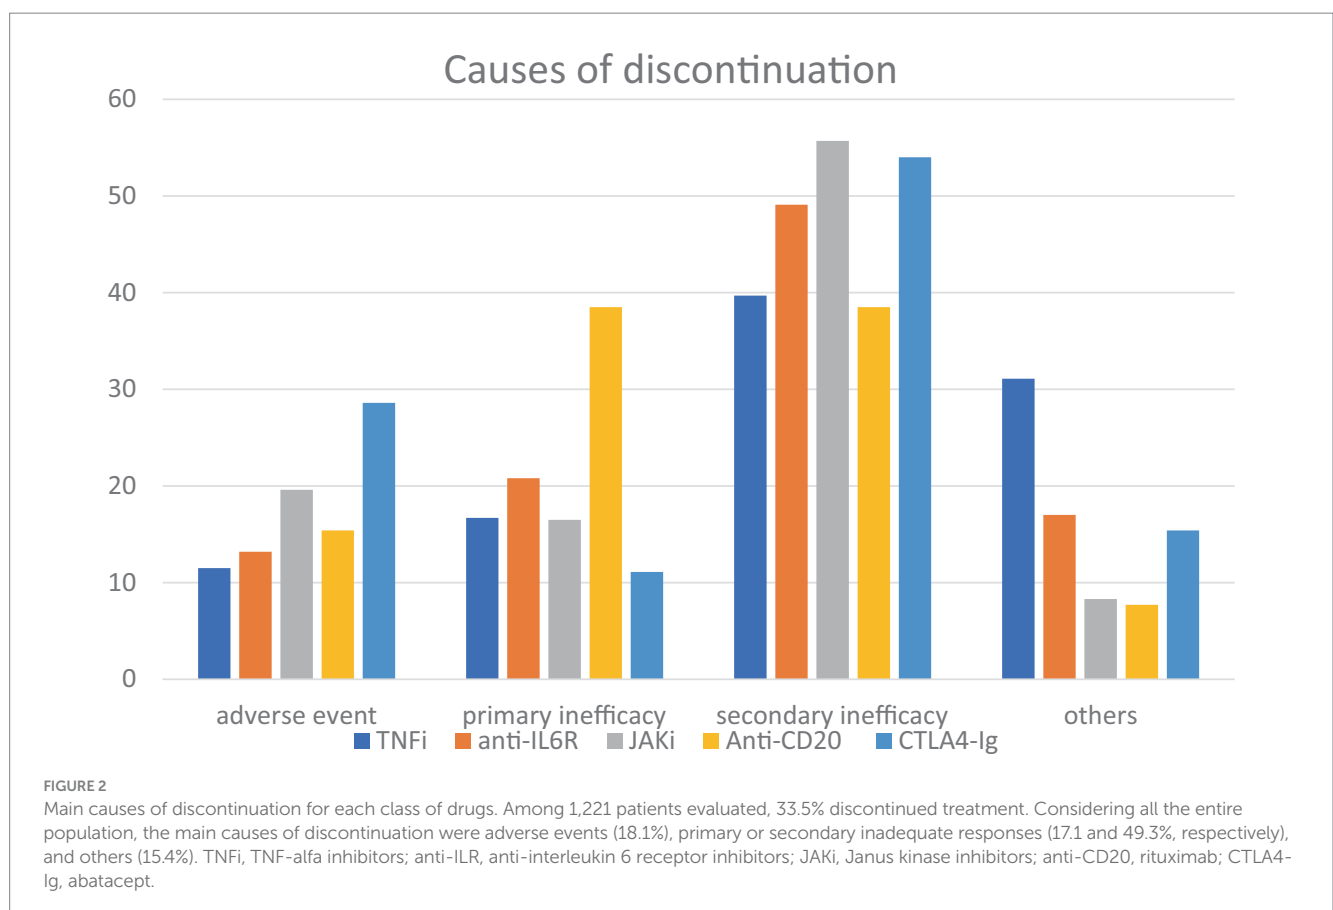

A few studies have specifically compared the retention rates of biologic DMARDs in elderly patients (15, 16), and then we aimed to evaluate possible differences in the persistence in therapy of different biologic and ts-DMARDs in patients older than 65 years and to investigate possible predictive factors for treatment failure for each drug.

Abatacept was the first b-DMARD prescribed (24.8% of the total) in our study. Despite the availability of cheaper biosimilar drugs, such as adalimumab and etanercept, abatacept was prescribed as a first-line biologic drug after conventional DMARDs in 45.9% of cases, suggesting that Italian rheumatologists might perceive abatacept as the safest option for elderly patients. Baricitinib and tofacitinib, more recently introduced in Italy, have also been prescribed to a large number of patients, similar to TNFi. On the contrary, RTX has been

TABLE 4 Factors associated with drug discontinuation according to a class of biologic or targeted synthetic DMARDs (multivariate analysis).

DMARDs, disease-modifying anti-rheumatic drugs; BMI, body mass index; JAKi, Janus kinases inhibitors; TNFi, TNF-alfa inhibitors; CDAI, clinical disease activity index.

prescribed only to a small number of patients. In this regard, the pandemic could have modified the therapeutic approach of Italian rheumatologists because of both the reduced access of elderly patients to hospitals and the potential negative effect of RTX on the response to the anti-SARS-CoV-2 vaccination (17–19).

Like for younger patients (20, 21), an insufficient clinical response remains the first cause of drug discontinuation in this specific population (22). Approximately half of patients showed a secondary loss of drug response. Clinical disease activity measured with CDAI and the number of comorbidities were the main factors associated with drug discontinuation. Of interest, combination therapy with a csDMARD, mainly MTX, was associated with longer persistence on therapy, but the association was not confirmed by multivariate analysis. This point could be relevant in elderly patients, in whom comorbidities and multi-therapies can increase the risk of side effects (1, 23). In this regard, monotherapy might be a driver of choice for JAKi and anti-IL6R, combined with a csDMARD, in less than half of patients.

Bechman et al. evaluated the survival rates of TNFi in combination therapy with MTX or not in RA patients older than 75 years. In biologic naïve patients ≥ 75 -years-old starting with TNFi, the authors did not observe an increased risk of discontinuation in patients treated with monotherapy (differently by younger patients included in the study). In elderly patients, this may be related to the phenomenon of immunosenescence, which induces a lower production of anti-drug antibodies (24, 25).

Specker et al. observed good safety and efficacy of tocilizumab (anti-IL6R) in RA patients >65 years old at baseline. Patients >65 years had higher disease activity scores, lower physical functioning, and a greater number of comorbidities at baseline. However, they had numerically greater reductions of CDAI over the course of treatment than patients <50 years. Furthermore, the presence of comorbidities did not modify the results of disease activity improvement (26).

Regarding abatacept, a small retrospective Japanese study reported no significant differences in the incidence of adverse events between younger and elderly RA patients (≥ 75 years), while the overall retention rate of CTLA4-Ig and infection-free survival were similar in the two groups. Finally, the most common cause of discontinuation was treatment inefficacy, independently of age (27, 28). Similar results were also described by Temmoku et al. in patients treated with a JAKi. No differences were reported in retention rate and causes of drug discontinuation in old (≥ 65 years) or very old (≥ 75) RA patients who initiated a JAKi (29).

In elderly patients from the ANSWER cohort study, abatacept and tocilizumab showed the highest retention rates, 78.1 and 66.8% at 36 months, respectively, and both showed a higher retention rate compared with TNFi (16).

Differently, in our study, abatacept was the drug with the best persistence in therapy (254.1 weeks, CI 95% 219.4–288.9) and a retention rate at 2 years of $66.3\% \pm 3.8$, but persistence in therapy of tocilizumab was similar to TNFi and significantly lower than abatacept.

A specific point to be addressed in elderly patients is the relevance of body weight in response to the therapy. In young patients, BMI is associated with lower effectiveness for many drugs (30, 31).

On the contrary, in our study, BMI was inversely associated with drug discontinuation. In elderly patients, maintenance of body weight is usually correlated with their health status, and a low BMI might be associated with sarcopenia (32). To reinforce this hypothesis, a very

low BMI (< 20) is associated with a high discontinuation rate in elderly RA patients treated with CTLA4-Ig.

Recently, the results of the Oral Surveillance trial suggested an association between tofacitinib and cardiovascular adverse events and malignancies rather than TNFi in patients with RA (33). Consequently, the European Medicine Agency (EMA) and the Food and Drug Administration modified the labeling of JAKi. Our data were collected before the labeling revision from EMA. Our results did not suggest any difference in safety between JAKi and different classes of b-DMARDs. In this regard, a careful evaluation of cardiovascular risk is mandatory for over 65 patients.

Our data were collected before the labeling change, and only future studies might clarify its possible impact on the prescription of JAKi in over 65 patients.

Finally, for each class of drugs, different factors associated with early discontinuation were identified. Despite the fact that we are far from true personalized therapy, some drivers of choice might be identified, suggesting a possible therapeutic algorithm according to the clinical features of the disease. For example, according to our results, abatacept and anti-IL-6R should be preferred in patients with high CDAI at baseline.

Further, the safety profile observed in this study suggests that the age of patients does not contraindicate the use of these drugs, reinforcing the opportunity to control disease activity in this group of patients.

Our study has some limitations; in fact, comorbidities are reported as “number of comorbidities” and cannot be further detailed. Therefore, we cannot advance any suggestion about the relative role of specific organ involvement (namely cardiovascular and pulmonary) on drug discontinuation. Moreover, smoking habits were not available for our analysis. On the other side, the current is one of the largest studies on elderly RA patients, allowing for the first time to compare the retention rates of biologics and ts-DMARDs in patients over 65 years old.

In conclusion, despite some limitations, our study allows us to provide an accurate picture of the treatment of elderly RA patients, which should be evaluated according to specific features such as comorbidities and age at diagnosis. While waiting for a clinical trial designed for this group of patients, registries could help us identify the best therapeutic approach and the effect of specific comorbidities on drug efficacy and safety in elderly RA patients.
