*Beauveria* is a very important fungal resource. Some *Beauveria* species have great economic and ecological value. Through surveying *Beauveria* in China and Thailand over the past 4 years, 15 *Beauveria* spp. were collected and identified. Three new species—namely, *B. polyrhachicola*, *B. songmingensis*, and *B. subscarabaeidicola*—were described and illustrated based on morphological characteristics and molecular data. The phylogenetic positions of the 15 species were evaluated according to phylogenetic inferences based on six loci (nrSSU, nrLSU, *TEF*, *RPB1*, *RPB2*, and *Bloc*). Nine species of *Beauveria* in our study were isolated from adult scarab beetles (Coleoptera: Scarabaeidae). The pathogenicity of the isolates from the *B. bassiana* complex and *B. scarabaeidicola* complex was determined with three bioassays using *B. mori* and *T. molitor* larvae, in addition to *Protaetia brevitarsis* adults. The results indicated that the *B. bassiana* complex isolates had great potential in the biocontrol of the three insects; by contrast, the *B. scarabaeidicola* complex isolates showed obvious host specificity and low virulence.

**Keywords:** Taxonomy, *Beauveria*, phylogenetic analyses, new species, biological control

## INTRODUCTION

*Beauveria* is a very important fungal resource, with some species having great economic and ecological value (Zimmermann, 2007; Rehner et al., 2011; Wang Y. et al., 2020). *Beauveria bassiana* (Bals.-Criv.) Vuill. and *B. brongniartii* (Sacc.) Petch are well-known environmentally safe alternatives to using chemical pesticides to control agricultural pests (Zimmermann, 2007; Rehner et al., 2011). *Beauveria pseudobassiana* S.A. Rehner and Humber has also been shown to have great potential in the biocontrol of numerous insect pests (Wang Y. et al., 2020). The entomopathogenic fungi *Beauveria* spp. are a class of environmentally friendly fungal pathogens that play an important role in controlling insect populations in nature (Luo et al., 2018; McKinnon et al., 2018). Some *Beauveria* species, as endophytes or soil and rhizosphere inhabitants, have been considered for potential use as biocontrol agents against plant pathogens by concerned practitioners, such as agriculturalists and plant pathologists. These species can produce an array of bioactive metabolites that limit the growth of some fungal plant pathogens and induce plant systemic resistance against the pathogenic bacterium (Ownley et al., 2010).

*Beauveria bassiana* is the most widely used fungus available commercially for controlling agricultural and forestry pests (Li et al., 2011). Products based on this species have been developed in many countries around the world (Goettel et al., 2005; Faria and Wraight, 2007; Li et al., 2011). However, a growing body of molecular evidence has demonstrated that *B. bassiana*, originally known as a generalist with a global distribution, encompasses cryptic lineages adapted to specific hosts or ecologies (Li et al., 2011; Rehner et al., 2011). Many initially identified *B. bassiana* isolates may belong to any of the species in the *B. bassiana* complex, such as *B. rudraprayagi* Y. Agrawal, Mual and Shenoy, *B. staphylinidicola* (Kobayasi and Shimizu) B. Shrestha, Kepler and Spatafora, and *B. peruviansis* D.E. Bustamante, M.S. Calderon, M. Oliva, and S. Leiva (Rehner et al., 2011; Agrawal et al., 2014; Kepler et al., 2017; Bustamante et al., 2019). Therefore, the abovementioned mycoinsecticide formulations of *B. bassiana* are not likely all based on *B. bassiana*.

*Beauveria scarabaeidicola* (Kobayasi) S.A. Rehner and Kepler is widely distributed in Oceania and Asia and named after its host adult beetle (Coleoptera: Scarabaeidae). It was originally described as *Cordyceps scarabaeicola* occurring in its sexual morph on an adult scarab beetle in New Guinea (Kobayasi and Shimizu, 1976). *Cordyceps scarabaeicola* has also been reported occasionally from many Asian countries, including China, Japan, and Korea (Shrestha et al., 2014). In an important phylogenetic study of *Beauveria*, a new entomopathogenic species, *B. sungii* S.A. Rehner and R.A. Humber, was described as a scarab-killing pathogen (hosts of all *B. sungii* isolates were identified as scarabs) (Rehner et al., 2011). Later, however, Shrestha et al. (2014) demonstrated that the telemorphic stage of *B. sungii* was *C. scarabaeicola* based on morphological and phylogenetic evidence. Because *C. scarabaeicola* was described earlier than *B. sungii*, Kepler et al. (2017) recommended *B. scarabaeicola* as the name of this species. Recently, Chen et al. (2019) proposed a new species, *B. yunnanensis*, a Chinese species parasitic on Lepidoptera pupa buried in soil that was a sister lineage to *B. scarabaeicola*.

During surveys of entomopathogenic fungi from different regions in Yunnan Province, China, and Chiang Rai Province, Thailand, over the past 4 years, approximately 15 *Beauveria* spp. were found and identified (Table 1). In this study, we aimed to: (1) reveal the hidden species diversity of the *B. bassiana* complex and *B. scarabaeidicola* complex based on phylogenetic analyses and morphological observation and (2) assess the biocontrol potential of species in the *B. bassiana* complex and *B. scarabaeidicola* complex through pathological tests on the lepidopteran *Bombyx mori* and the coleopteran *Tenebrio molitor* larvae as well as *Protaetia brevitarsis* adults.

## MATERIALS AND METHODS

### Soil and Specimen Collection

All the soil samples and the majority of *Beauveria* specimens were collected from Yunnan Province in China. Some specimens were collected from Chiang Rai Province in Thailand. Soil samples and specimens were noted and

photographed in the fields, and then carefully placed in plastic containers at low temperature. Afterward, they were carried to the laboratory and stored at 4°C before examination and isolation.

### Fungal Isolation and Culture

*Beauveria* strains were isolated from the soil samples using the *Tenebrio molitor* baiting method (Keyser et al., 2015). Conidia developing on insect cadavers were transplanted onto plates of potato dextrose agar (PDA; potato 200 g/L, dextrose 20 g/L, agar 20 g/L) and cultured at 25°C. Teleomorph specimens were rinsed with tap water, washed with sterile distilled water, and then dried on sterile filter paper. To obtain axenic cultures, white tissue inside the sclerotia of the teleomorph specimens was removed and inoculated onto PDA plates using a sterilized dissecting knife. Colonies of the isolated filamentous fungi appearing in the culture were transferred onto fresh PDA media. The purified fungal strains were maintained in a culture room at 25°C or transferred to PDA slants and stored at 4°C. Specimens were deposited in the Yunnan Herbal Herbarium (YHH) at the Institute of Herb Biotic Resources of Yunnan University. Cultures were stored in the Yunnan Fungal Culture Collection (YFCC) at the Institute of Herb Biotic Resources of Yunnan University.

### Morphological Observations

Specimens were examined using an Olympus SZ61 stereomicroscope (Olympus Corporation, Tokyo, Japan). Cultures on PDA slants were transferred to PDA plates and then incubated at 25°C for 14 days. For morphological evaluation, microscope slides were prepared by placing mycelia from the cultures on PDA medium blocks (5 mm diameter) and then overlaid with a coverslip. Medan dye solution was used to observe asci and ascospores. Other structures were mounted in water. Micro-morphological observations and measurements were performed using a light microscope (CX40, Olympus Corporation, Tokyo, Japan) and a scanning electron microscope (Quanta 200 FEG, FEI Company, Hillsboro, United States). Length to width ratios are given as Q. Mean values for length, width, and Q are indicated by  $L^m$ ,  $W^m$ , and  $Q^m$ , respectively.

### DNA Extraction, PCR and Sequencing

Specimens and axenic living cultures were prepared for DNA extraction. Genomic DNA was extracted using the Genomic DNA Purification Kit (Qiagen GmbH, Hilden, Germany) according to the manufacturer's protocol. The primer pair nrSSU-CoF and nrSSU-CoR was used to amplify a fraction of the nuclear ribosomal small subunit (nrSSU) (Wang et al., 2015). Primer pair LR5 and LR0R (Vilgalys and Hester, 1990; Rehner and Samuels, 1994) was used to amplify a fraction of the nuclear ribosomal large subunit (nrLSU) and EF1 $\alpha$ -EF and EF1 $\alpha$ -ER (Bischoff et al., 2006; Sung et al., 2007) for the translation elongation factor 1 $\alpha$  (*TEF*). For amplification of the largest and second largest subunits of the RNA polymerase II (*RPB1* and *RPB2*), PCR primer pairs RPB1-5'F/RPB1-5'R and RPB2-5'F/RPB2-5'R (Bischoff et al., 2006; Sung et al., 2007)

**Boldface:** data generated in this study. <sup>T</sup>ex-type material.

were employed. The *Bloc* fragment was amplified using primer pair B5.1F/B3.1R (Rehner et al., 2006). All the PCR reactions were performed in a final volume of 50  $\mu$ L and contained 25  $\mu$ L of 2  $\times$  Taq PCR Master Mix (Tiangen Biotech Co. Ltd, Beijing, China), 0.5  $\mu$ L of each primer (10  $\mu$ M), 1  $\mu$ L of genomic DNA, and 23  $\mu$ L of RNase-free water. Target gene amplification and sequencing were performed according to the methods described in our previous study (Wang Y. B. et al., 2020).

## Phylogenetic Analyses

Phylogenetic analyses were based on six gene (*nrSSU*, *nrLSU*, *TEF*, *RPB1*, *RPB2*, and *Bloc*) sequences. The sequences were retrieved from GenBank and combined with those generated in our study. Taxon information and GenBank accession numbers were provided in **Supplementary Table 1** and **Table 1**. Sequences were aligned using MAFFT v.7.<sup>1</sup> After alignment, the sequences of the genes were concatenated. Conflicts among the six genes were tested using PAUP\* 4.0b10 (Swofford, 2002). The results revealed that the phylogenetic signals in the six genes were not in conflict. The data partitions were defined for the combined dataset using PartitionFinder V1.1.1 (Lanfear et al., 2012). Phylogenetic analyses were conducted using BI and ML methods employing MrBayes v3.1.2 and RaxML 7.0.3, respectively (Ronquist and Huelsenbeck, 2003; Stamatakis et al., 2008). The BI analysis was run on MrBayes v3.1.2 for five million generations using a GTR+G+I model determined by jModelTest version 2.1.4 (Darriba et al., 2012). GTR+I was selected as the optimal model for ML analysis, and 1,000 rapid bootstrap replicates were performed on the dataset.

The first analysis based on the combined five-gene (*nrSSU*+*nrLSU*+*TEF*+*RPB1*+*RPB2*) dataset was performed using the following taxa: *Akanthomyces*, *Amphichorda*, *Ascoplyporus*, *Beauveria*, *Blackwellomyces*, *Cordyceps*, *Gibellula*, *Hevansia*, *Samsoniella*, and *Simplicillium*. Two taxa of *Trichoderma* were designated as outgroups. The second analysis based on the combined four-gene (*TEF*+*RPB1*+*RPB2*+*Bloc*) sequences was performed using *Beauveria* taxa.

We applied a (phylo-) genetic distance matrix calculation for the combined four-gene (*TEF*+*RPB1*+*RPB2*+*Bloc*) sequences to assess species boundaries in the *B. bassiana* complex and *B. scarabaeidicola* complex (**Table 2**). The pairwise genetic distances of most *Beauveria* lineages (**Supplementary Table 2**) were measured based on the Kimura 2-parameter model using MEGA6 software (Tamura et al., 2013).

## Conidial Viability of *Beauveria* spp. Isolates

A total of 19 *Beauveria* spp. isolates (**Table 3**) were analyzed for their conidial viability using the method described by Imoulan et al. (2011). The conidial viability of each isolate was confirmed by inoculating three tubes of 3 ml PDB media (potato 200 g/L, dextrose 20 g/L) with 0.1 ml of conidia suspension ( $3 \times 10^6$

conidia/ml). Only isolates with conidial viability greater than 65% were tested for pathogenicity toward *B. mori*, *T. molitor*, and *P. brevitarsis*.

## Virulence Assay of *Beauveria* spp. Isolates

A total of 10 *Beauveria* spp. isolates from the *B. bassiana* complex and *B. scarabaeidicola* complex were tested for their pathogenicity to *B. mori* and *T. molitor* larvae in addition to *P. brevitarsis* adults. Conidia for each isolate were obtained from 4-week-old cultures grown on malt extract agar plates, suspended in a sterile aqueous solution of 0.01% Tween 80, and mixed vigorously until homogeneous conidial suspensions were produced. Quantification of the conidia was performed using a hemocytometer under a light microscope at 400 $\times$  magnification. All of the suspensions were adjusted to  $1 \times 10^8$  conidia/ml. The tested insects were individually placed in sterilized rearing boxes and 10  $\mu$ l of conidial suspension was applied to the surface of each insect. A diet was provided for each insect and renewed as needed. Control groups were treated with the same volume of a sterile aqueous solution of 0.01% Tween 80. The test was replicated three times with 50 insects per replicate. All of the test groups were kept at 25°C under a 12:12 h photoperiod cycle. The numbers of dead insects were recorded every 12 h for a 30 day period, which was used to determine the percentage of mortality. Cadavers were removed, immediately surface-disinfected, and individually placed and maintained in rearing box chambers. Mycelium samples from cadavers were aseptically removed and cultured on PDA for microscope examination, DNA extraction, and *TEF* sequencing to confirm that mortality was caused by the inoculated fungal strain.

## RESULTS

### Sequencing and Phylogenetic Analyses

The combined five-gene dataset included sequences from 123 fungal taxa. The final dataset consisted of 5,001 bp of sequence data (*nrSSU* 1,138 bp, *nrLSU* 910 bp, *TEF* 1,047 bp, *RPB1* 781 bp, and *RPB2* 1,125 bp). Eleven well-supported clades were recognized based on both Bayesian inference (BI) and maximum likelihood (ML) analyses of the combined five-gene dataset of 123 taxa from Cordycipitaceae and *Trichoderma*, which accommodate species of the genera *Akanthomyces*, *Amphichorda*, *Ascoplyporus*, *Beauveria*, *Blackwellomyces*, *Cordyceps*, *Gibellula*, *Hevansia*, *Samsoniella*, *Simplicillium*, and *Trichoderma* (**Supplementary Figure 1**). The phylogenetic analyses also revealed the species diversity of the *B. bassiana* complex and *B. scarabaeidicola* complex in *Beauveria* clades. This suggested that the groups composed of the *B. bassiana* complex and *B. scarabaeidicola* complex should be genetically composed of at least four species (**Supplementary Figure 1**). Phylogenetic analyses based on combined partial *TEF*+*RPB1*+*RPB2*+*Bloc* sequences consisting of 59 fungal taxa resolved most *Beauveria* lineages in separate terminal branches (**Figure 1**). This

**TABLE 2** | Genetic distance (p-distances) of species in the *B. bassiana* complex and *B. scarabaeidicola* complex.

Group	Taxa	Marker
		<i>TEF+RPB1+RPB2+Bloc</i>
The <i>B. bassiana</i> complex	<i>B. bassiana</i> — <i>B. peruviansis</i>	0.015
	<i>B. bassiana</i> — <i>B. polyrhachicola</i>	0.019
	<i>B. bassiana</i> — <i>B. rudraprayagi</i>	0.042
	<i>B. bassiana</i> — <i>B. staphylinidicola</i>	0.010
	<i>B. peruviansis</i> — <i>B. polyrhachicola</i>	0.011
	<i>B. peruviansis</i> — <i>B. rudraprayagi</i>	0.044
	<i>B. peruviansis</i> — <i>B. staphylinidicola</i>	0.015
	<i>B. polyrhachicola</i> — <i>B. rudraprayagi</i>	0.045
	<i>B. polyrhachicola</i> — <i>B. staphylinidicola</i>	0.019
	<i>B. rudraprayagi</i> — <i>B. staphylinidicola</i>	0.045
The <i>B. scarabaeidicola</i> complex	<i>B. scarabaeidicola</i> — <i>B. songmingensis</i>	0.013
	<i>B. scarabaeidicola</i> — <i>B. subscarabaeidicola</i>	0.017
	<i>B. scarabaeidicola</i> — <i>B. yunnanensis</i>	0.014
	<i>B. songmingensis</i> — <i>B. subscarabaeidicola</i>	0.012
	<i>B. songmingensis</i> — <i>B. yunnanensis</i>	0.013
	<i>B. subscarabaeidicola</i> — <i>B. yunnanensis</i>	0.013

revealed a similar tree and clustering topology, as shown in **Supplementary Figure 1**. It was proposed that the two strains YFCC 859 and YFCC 867, which formed a strongly supported clade, might be a new species in the *B. bassiana* complex, named *B. polyrhachicola* (**Figure 1**). Our analyses also revealed that two newly discovered species, *B. songmingensis* and *B. subscarabaeidicola*, were phylogenetically clustered with *B. yunnanensis* and *B. scarabaeidicola*, but they were clearly distinguished from the latter two by forming two separate clades in the *B. scarabaeidicola* complex (**Figure 1** and **Supplementary Figure 1**). The genetic divergence comparisons showed that the minimum threshold (p-distance) to distinguish genetic species in *Beauveria* was 0.010 for the combined four-gene (*TEF+RPB1+RPB2+Bloc*) sequences, as occurred between *B. araneola* and *B. medogensis*, between *B. asiatica* and *B. majiangensis*, between *B. australis* and *B. brongniartii*, and between *B. bassiana* and *B. staphylinidicola* (**Table 2** and **Supplementary Table 2**). These results also suggested that: (1) the *B. bassiana* complex, which is made up of five species, should include *B. bassiana*, *B. peruviansis*, *B. polyrhachicola*, *B. rudraprayagi*, and *B. staphylinidicola* and (2) the *B. scarabaeidicola* complex should be composed of four species, including *B. scarabaeidicola*, *B. songmingensis*, *B. subscarabaeidicola*, and *B. yunnanensis*.

## Morphological Features

The morphological characteristics of the three new species as well as photomicrographs of morphological structures are shown in **Figures 2–4**. The detailed fungal morphological descriptions are provided in the Taxonomy section.

## Conidial Viability of the *Beauveria bassiana* Complex and *Beauveria scarabaeidicola* Complex Isolates

Percentage of conidial germination was used to determine conidial viability. The conidial viability of the *B. bassiana* complex isolates was high, but the highest value ( $\bar{x} = 95\%$ ) was found on isolates of YFCC 844 from soil (see **Table 3**). The values of the conidial viability of the isolates in the *B. scarabaeidicola* complex were significantly lower than those in the *B. bassiana* complex. Only four *B. scarabaeidicola* complex isolates with conidial viability were greater than 65%, and their conidial viability values were not significantly different ( $P < 0.05$ ).

## Virulence of the *Beauveria bassiana* Complex and *Beauveria scarabaeidicola* Complex Isolates

Ten isolates had conidial viability greater than 65%. These isolates were then selected for pathogenicity tests against *B. mori* and *T. molitor* larvae as well as *P. brevitarsis* adults (**Table 4**). The *B. bassiana* complex isolates were shown to have great potential for use in the management of various insect pests; by contrast, the *B. scarabaeidicola* complex isolates showed obvious host specificity and low virulence. All tested isolates in the *B. bassiana* complex inflicted mycoses on *B. mori* and *T. molitor* larvae and caused over 80% mortality, whereas those in the *B. scarabaeidicola* complex did not. It was determined that the 10 isolates were pathogenic to *P. brevitarsis* adults but demonstrated different levels of virulence. Like the conidial viability, the mortalities of *P. brevitarsis* adults caused by the *B. scarabaeidicola* complex isolates were significantly lower than those of isolates in the *B. bassiana* complex ( $P < 0.05$ ), strengthening the hypothesis that the virulence of certain entomopathogenic fungi is related to their conidial viability (Butt et al., 1994; Fernandes et al., 2007). Additionally, *B. bassiana* YFCC 844, which was isolated from soil and exhibited the highest conidial viability, showed high virulence against *B. mori* and *T. molitor* larvae, as well as *P. brevitarsis* adults, causing  $(94.00 \pm 1.15)\%$  mortality against *B. mori* larva,  $(95.33 \pm 1.45)\%$  mortality against *T. molitor* larva, and  $(79.00 \pm 1.53)\%$  mortality against *P. brevitarsis* adults (**Table 4**). Mycelium samples from cadavers were aseptically removed and cultured on PDA. Microscopic examination recovered the same morphological characters of conidiophores and conidia as the inoculated fungal strain. Further, *TEF* sequenced from DNA extracted from recultures of the external mycelium of cadavers were found to match that of inoculated strain perfectly.

## TAXONOMY

*Beauveria polyrhachicola* H. Yu & Y. Wang, sp. nov. **Figure 2**

Mycobank number 841450.

Etymology: “*polyrhachicola*” refers to the host (*Polyrhachis* sp.).

Sexual morph: Undetermined.

**TABLE 3** | Conidial viability of *Beauveria* spp. isolates used in this study.

Group	Species and isolate	Host/substrate	Location	Conidial viability $\pm$ SE (%) <sup>#</sup>

<sup>#</sup>Only isolates with % of conidial viability  $\geq$  65% were significance tested. Different lowercase letters in the same column indicate significant differences at 5% level.

**Asexual morph:** Colonies on PDA reached 20–38 mm in diameter after 14 days at 25°C, white, circular, velutinous, and closely appressed to the agar surface; reverse yellowish white. Odor indistinct. Vegetative hyphae septate, branched, hyaline, smooth-walled, 1.2–2.3  $\mu$ m wide. Conidiogenous cells, long cylindrical to long flask shaped, solitary or occurring in dense lateral clusters, base cylindrical to ampulliform and 1.4–3.0  $\mu$ m wide, sympodially branched neck tapering into a long, slender, denticulate rachis, produced laterally on aerial hyphae or from subtending cells, 11.8–40.9  $\times$  1.4–3.0  $\mu$ m. Conidia 2.0–3.8  $\times$  1.7–2.6  $\mu$ m, Q = 1.0–1.8  $\mu$ m ( $L^m$  = 2.7  $\mu$ m,  $W^m$  = 2.1  $\mu$ m,  $Q^m$  = 1.3), globose, subglobose, slightly ellipsoid, oblong, or cylindrical, hyaline, aseptate, walls smooth and thin.

**Type:** Thailand, Chiang Rai Province, Khun Tan District (19.9233°N, 100.3133°E, 396 m above sea level), on an adult worker of *Polyrhachis* sp. emerging from leaf litter on the forest floor, May 2019, collected by Preeyanat Hongthong (holotype: YHH 859; ex-type living culture: YFCC 859).

**Distribution:** Khun Tan District, Chiang Rai Province, Thailand; Simao District, Yunnan Province, China.

**Other material examined:** China, Yunnan Province, Puer City, Simao District (22.7113°N, 100.9579°E, 1,360 m above sea level), on an adult worker of *Polyrhachis* sp. emerging from leaf litter on

the forest floor, August 26, 2021, Yao Wang (YHH 867, 868; living culture: YFCC 867).

**Notes:** Regarding phylogenetic relationships, *B. polyrhachicola* forms a distinct lineage in the *B. bassiana* complex, and it is closely related to *B. peruviansis*, *B. staphylinidicola*, *B. bassiana*, and *B. rudraprayagi* (Figure 1). Morphologically, *B. polyrhachicola* is similar to *B. bassiana*, *B. kipukae*, *B. pseudobassiana*, *B. varroae*, and *B. peruviansis* in terms of the shape and size of the conidia (Rehner et al., 2011; Bustamante et al., 2019). However, *B. polyrhachicola* can be distinguished from them by its long conidiogenous cells (11.8–40.9  $\times$  1.4–3.0  $\mu$ m).

***Beauveria songmingensis* H. Yu & Y. Wang, sp. nov. Figure 3**  
Mycobank number 841451.

**Etymology:** named after the location Songming County where this species was collected.

**Sexual morph:** Undetermined.

**Asexual morph:** Colonies on PDA reaching 20–35 mm in diameter after 14 days at 25°C, yellowish white, pale yellow, or light yellow, circular; reverse pale yellow, light yellow, or shades of orange to deep orange. Odor indistinct. Vegetative hyphae septate, branched, hyaline or translucent pale yellow, smooth-walled, 2.2–4.5  $\mu$ m wide. Conidiogenous

cells, cylindrical to long flask shaped, solitary but usually in dense clusters of five or more, base cylindrical to ampulliform and 2.7–5.6  $\mu\text{m}$  wide, apex with an indeterminate 1  $\mu\text{m}$  wide geniculate, denticulate rachis, produced laterally on aerial hyphae or from subtending cells, mostly 9.6–34.1  $\times$  2.7–5.6  $\mu\text{m}$ . Conidia 3.6–6.8  $\times$  2.8–3.9  $\mu\text{m}$ ,  $Q = 1.0$ –2.0  $\mu\text{m}$  ( $L^m = 5.6$   $\mu\text{m}$ ,  $W^m = 3.4$   $\mu\text{m}$ ,  $Q^m = 1.6$ ), subglobose, broadly ellipsoid, ellipsoid, or oblong, hyaline, aseptate, walls smooth and thin.

Type: China, Yunnan Province, Kunming City, Songming County, Dashao Village (25.3924°N, 102.5589°E, 2,700 m

above sea level), on an adult of *Pseudosymmachia flavescens* (Coleoptera: Scarabaeidae), August 12, 2018, collected by Yao Wang, (holotype: YHH 860; ex-type living culture: YFCC 860).

Distribution: at present known only in Dashao Village, Songming County, Yunnan Province, China.

Other material examined: China, Yunnan Province, Kunming City, Songming County, Dashao Village (25.3924°N, 102.5589°E, 2,700 m above sea level), on an adult of *Pseudosymmachia* sp. emerging from leaf litter on the forest floor, August 12, 2018, Yao Wang (YHH 848, 861; living culture: YFCC 848, 861).

**FIGURE 3 |** Morphology of *Beauveria songmingensis*. **(A)** The type specimen (YHH 860). **(B,C)** *Protactia brevitarsis* adults infected by *B. songmingensis*. **(D,E)** Culture character on PDA medium. **(F–I)** Conidiogenous cells and conidia. Scale bars: **(A–C)** = 10 mm; **(D,E)** = 20 mm; **(F–H)** = 20  $\mu\text{m}$ ; **(I)** = 10  $\mu\text{m}$ .

Notes: Morphologically, *B. songmingensis* resembles the phylogenetically sister species *B. scarabaeidicola* and *B. subscarabaeidicola*. They were found to be parasitic on adult beetles (Coleoptera: Scarabaeidae), and they could be easily recognized by their distinctly yellow colony pigmentation and ellipsoid or oblong conidia. However, our morphological observation revealed a significant difference of conidia sizes between *B. songmingensis* ( $3.6\text{--}6.8 \times 2.8\text{--}3.9 \mu\text{m}$ ) and *B. scarabaeidicola* ( $2.5\text{--}3.5 \times 1.5\text{--}2.5 \mu\text{m}$ ). *B. songmingensis* differs from *B. subscarabaeidicola* by its long conidiogenous cells

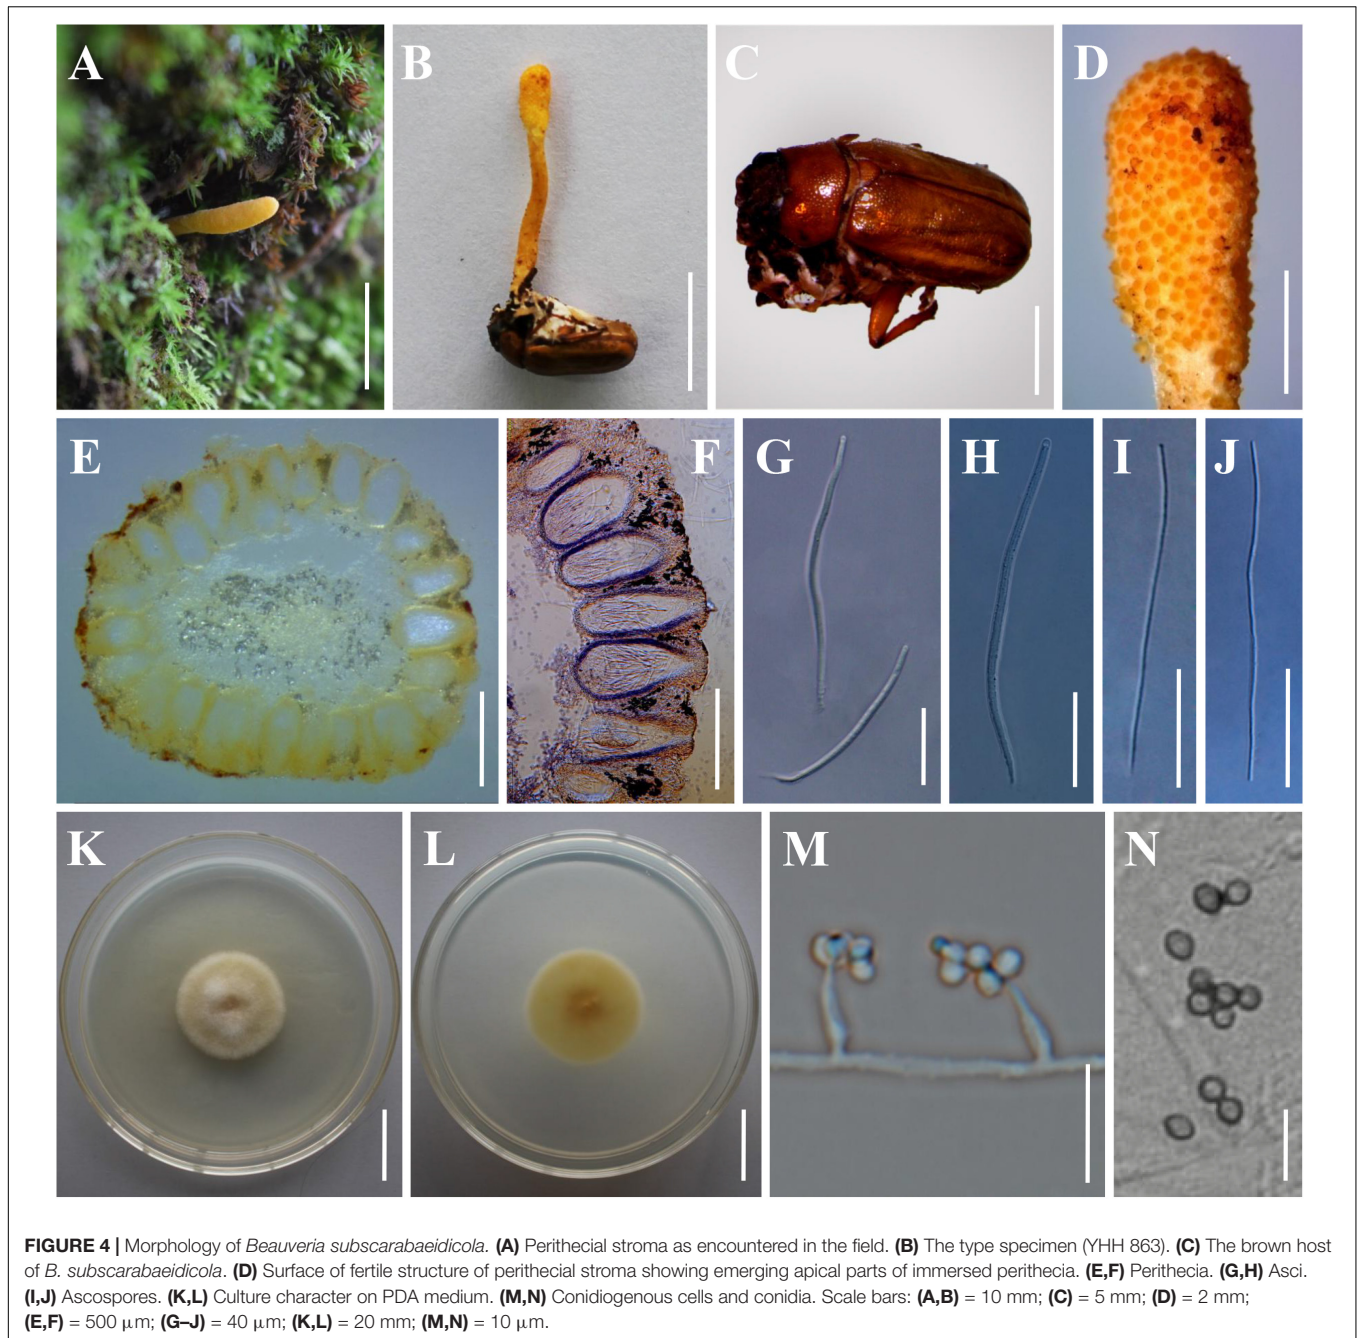

( $9.6\text{--}34.1 \times 2.7\text{--}5.6 \mu\text{m}$ ) and large conidia ( $3.6\text{--}6.8 \times 2.8\text{--}3.9 \mu\text{m}$ ). Both morphological study and phylogenetic analyses of combined *TEF*, *RPB1*, *RPB2*, and *Bloc* sequence data support that this fungus is a distinctive species in the genus *Beauveria*.

***Beauveria subscarabaeidicola* H. Yu, Y. Wang & Q. Fan, sp. nov. Figure 4**

Mycobank number 841452.

Etymology: “*subscarabaeidicola*” refers to morphologically resembling *Beauveria scarabaeidicola* but phylogenetically distinct.

Sexual morph: Stromata solitary, fleshy, pale yellow to orange, arising on adult scarab beetles buried in soil or decayed leaves, 30–45 mm long. Stipes cylindrical to clavate, yellowish white to deep yellow, 1.1–2.0 mm wide. Fertile parts clavate, being slightly wider than and indistinct from the stipes, deep yellow to orange, 5.2–26.0 mm long, 1.4–3.3 mm wide. Perithecia semi-immersed and crowded at the apex of the stromata, ampulliform, pyriform, ovoid to oblong, 265–700  $\times$  180–320  $\mu\text{m}$  ( $n = 50$ ). Asci hyaline, cylindrical, 124.5–257.4  $\times$  3.7–5.2  $\mu\text{m}$  ( $n = 50$ ). Apical caps prominent, hemiglobose, 2.7–3.9  $\mu\text{m}$  wide, 2.4–3.2  $\mu\text{m}$  high ( $n = 50$ ). Ascospores hyaline, filiform, multi-septate,

finally breaking into secondary ascospores, 75.6–188.5  $\times$  1.0–1.5  $\mu\text{m}$  ( $n = 30$ ). Secondary ascospores cylindrical, hyaline, 6.9–11.2  $\times$  1.0–1.5  $\mu\text{m}$  ( $n = 50$ ).

Asexual morph: Colonies on PDA reaching 28–42 mm in diameter after 14 days at 25°C, yellowish white, pale yellow, or light yellow, circular; reverse pale yellow, light yellow, or shades of orange to deep orange. Odor indistinct. Vegetative hyphae septate, branched, hyaline or translucent pale yellow, smooth-walled, 1.2–2.5  $\mu\text{m}$  wide. Conidiogenous cells, phialidic, solitary but usually in dense clusters of five or more, base subspherical to ampulliform and 2.8–5.0  $\mu\text{m}$  wide, apex with an indeterminate

Conidia 2.6–4.2 × 1.9–3.5 μm, Q = 1.0–1.4 μm (L<sup>m</sup> = 3.4 μm, W<sup>m</sup> = 2.8 μm, Q<sup>m</sup> = 1.2), subglobose or broadly ellipsoid, hyaline, aseptate, walls smooth and thin.

Type: China, Yunnan Province, Kunming City, Songming County, Dashao Village (25.2398°N, 102.5617°E, 2,697 m above sea level), on an adult of *Anomala exoleta* (Coleoptera: Scarabaeidae), July 23rd, 2019, collected by Dexiang Tang, (holotype: YHH 863; ex-type living culture: YFCC 863).

Distribution: at present known only from Dashao Village, Songming County, Yunnan Province, China.

Other material examined: China, Yunnan Province, Kunming City, Songming County, Dashao Village (25.2398°N, 102.5617°E, 2,697 m above sea level), on an adult of *Anomala exoleta*, July 23, 2019, Dexiang Tang (YHH 864; living culture: YFCC 864).

Notes: *Beauveria subscarabaeidicola* is practically indistinguishable in morphology to *B. scarabaeidicola*. Our morphological observation revealed no significant differences in the morphological characteristics of teleomorph and anamorph between the two species (Kobayasi and Shimizu, 1976; Rehner et al., 2011; Shrestha et al., 2014). The lack of diagnostic morphological features to distinguish *B. subscarabaeidicola* and *B. scarabaeidicola* was overcome by delimiting the two species using DNA-based methodologies.

## DISCUSSION

It is generally agreed that distinguishing individual *Beauveria* species can be difficult using only morphological characters, as several species in the genus are morphologically cryptic

species. In this study, we conducted a comprehensive investigation of the cryptic species diversity of the *B. bassiana* complex and *B. scarabaeidicola* complex. The molecular phylogeny clearly suggested the existence of distinct species in the *B. bassiana* complex and *B. scarabaeidicola* complex that we accordingly propose as new species: *B. polyrhachicola* (Figure 2), *B. songmingensis* (Figure 3), and *B. subscarabaeidicola* (Figure 4). *Beauveria polyrhachicola* is practically indistinguishable in morphology from other members of the *B. bassiana* complex. The shape and size of the conidia and the colony color of *B. polyrhachicola*, among other morphological features, have been observed in *B. bassiana*, *B. rudraprayagi*, *B. staphylinidicola*, and *B. peruviansis* (Rehner et al., 2011; Agrawal et al., 2014; Kepler et al., 2017; Bustamante et al., 2019). In the *B. scarabaeidicola* complex, the macromorphology of *B. scarabaeidicola*, *B. songmingensis*, and *B. subscarabaeidicola* is very similar, and thus species cannot be distinguished visually. The macroscopic and microscopic observations performed during our investigation revealed the extensive overlap in morphological characters and the lack of distinctive phenotypic variation, supporting the notion of cryptic species in a species complex.

At present, multi-locus phylogenetic analyses have gained importance in delimiting the species within the entomopathogenic fungi *Beauveria*. Rehner et al. (2011) divided *B. bassiana* s. lat. and *B. brongniartii* s. lat. into several cryptic species and described six new species based on the Bloc nuclear intergenic region and three nuclear genes encoding elongation factor 1-a (*TEF*), RNA polymerase II largest subunit (*RPB1*), and RNA polymerase II second largest subunit (*RPB2*). Subsequently, more than seven new species and new

combinations were confirmed using combined analysis of the four-locus sequence data (Zhang et al., 2012; Chen et al., 2013, 2017, 2018; Agrawal et al., 2014; Robène-Soustrade et al., 2015; Imoulan et al., 2016). In more recent studies, six species were added to the genus based on multilocus (nrSSU, nrLSU, *TEF*, *RPB1*, and *RPB2*) sequence data: *B. acridophila*, *B. blattidicola*, *B. diapheromeriphila*, *B. locustiphila*, *B. scarabaeidicola*, and *B. staphylinidicola* (Kepler et al., 2017). In this study, we analyzed most species of the newly circumscribed genus *Beauveria* based on phylogenetic inferences of six nuclear molecular markers (nrSSU, nrLSU, *TEF*, *RPB1*, *RPB2*, and *Bloc*). Phylogenetic analyses based on the five-gene (nrSSU, nrLSU, *TEF*, *RPB1*, and *RPB2*) dataset and the combined four-gene (*TEF*+*RPB1*+*RPB2*+*Bloc*) sequences produced trees with similar topologies that resolved most *Beauveria* lineages in separate terminal branches (Figure 1 and Supplementary Figure 1). The results of the present work indicate that the first dataset was conducive to determining the phylogenomic relationships between *Beauveria* and its related genera, and the use of the latter was essential to establish robust *Beauveria* species boundaries, particularly the *B. bassiana* complex and *B. scarabaeidicola* complex.

Scarab beetles are leaf and root feeding pests of grasses, grains, sugarcane, strawberry, potato tubers, and young nursery plants (Crocker et al., 1996; Yokoyama et al., 1998). Based on the published literature, there are about six *Beauveria* spp. that parasitize adult scarab beetles: *B. asiatica*, *B. bassiana*, *B. brongniartii*, *B. majiangensis*, *B. pseudobassiana*, and *B. scarabaeidicola* (Rehner et al., 2011; Kepler et al., 2017; Chen et al., 2018; Khonsanit et al., 2020; Wang Y. et al., 2020). Here, we identified an extension of the members to also include *B. malawiensis*, *B. songmingensis*, *B. subscarabaeidicola*, and *B. yunnanensis*, as shown in Figure 1. Chen et al. (2019) emphasized that hosts of *B. yunnanensis* isolates were Lepidoptera pupae. However, our morphological observations of specimens from a type locality of *B. yunnanensis* indicated that their hosts were adult scarab beetles. Moreover, the host of *B. yunnanensis* was not shown in their publication (Chen et al., 2019). It seems that the host of Lepidoptera pupa is doubtful. There is reason to believe that members of the *B. scarabaeidicola* species complex are host-specific.

Not all scarab-killing pathogens are suitable for mycoinsecticide formulations that control scarab beetles. Our data suggested that the *B. scarabaeidicola* complex isolates showed low virulence. In addition, mortalities in *P. brevitarsis* adults caused by the *B. scarabaeidicola* complex isolates were significantly lower than those of isolates in the *B. bassiana* complex. Additional research is needed to determine the effectiveness of other species before future consideration of isolates for biological pest control.

## CONCLUSION

The *B. bassiana* complex and *B. scarabaeidicola* complex, as special groups in the genus *Beauveria*, are rich in species

diversity and have a wide distribution in nature. The *B. bassiana* complex, which is made up of five species, is a cosmopolitan group of soilborne necrotrophic arthropod-pathogenic fungi that have been shown to have great potential for the management of various insect pests. The *B. scarabaeidicola* complex is composed of pathogens specific to scarab beetles, and it is found on leaf litter or buried in soil. Species in this complex are morphologically highly similar and can hardly be distinguished macroscopically. In this study, we reported the discovery and description of three new species: *B. polyrhachicola*, which was found in the *B. bassiana* complex, and *B. songmingensis* and *B. subscarabaeidicola*, which were found in the *B. scarabaeidicola* complex. In addition, 10 species of *Beauveria* were found to be parasitic on scarab beetles. However, not all members are suitable for mycoinsecticide formulations for controlling scarab beetles. Our data suggested that the *B. scarabaeidicola* complex isolates showed obvious low virulence. Additionally, the mortality of *Protaetia brevitarsis* adults caused by the *B. scarabaeidicola* complex isolates was significantly lower than that of isolates in the *B. bassiana* complex.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in GenBank. The accession numbers can be found in the article/Supplementary Material.

## AUTHOR CONTRIBUTIONS

YW and HY: conceptualization. YW: methodology, writing—original draft preparation, and formal analysis. YW and QF: software. QF, W-QZ, and DW: validation. YW, DW, D-XT, PH, and HY: investigation. YW, D-XT, and PH: resources. HY: writing—review and editing and funding acquisition. All authors reviewed and approved the final manuscript.

## FUNDING

This work was supported by the National Natural Science Foundation of China (No. 31870017, 31760011, and 32160005) and the Department of Science and Technology of Yunnan Province [No. 2018FY001(-006)].

## ACKNOWLEDGMENTS

We thank Dr. Yuan-Bing Wang for help in naming the new fungal species.
