Cyanidin-3-O-glucoside (C3G) is the most widely distributed anthocyanin and it can reportedly reduce the risk of osteoporosis, but the molecular mechanism by which C3G promotes bone formation is poorly understood. In the current study, RNA sequencing (RNA-seq) was used to investigate the mechanism of action of C3G in osteogenesis. MC3T3-E1 mouse osteoblasts were divided into a C3G (100  $\mu\text{mol/L}$ )-treated group and a vehicle-treated control group, and differentially expressed genes (DEGs) in groups were evaluated *via* RNA-seq analysis. The functions of the DEGs were evaluated by Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses, and the genes were validated by quantitative real-time PCR. The RNA-seq analysis identified 34 genes that were upregulated in C3G-treated cells compared to vehicle-treated cells, and 17 that were downregulated. GO and KEGG pathway analyses indicated that these genes were highly enriched in functions related to lysosomes and glycolipid biosynthesis, among others. The differential expression of ATPase H<sup>+</sup>-transporting V0 subunit C (*Atp6v0c*), chemokine (C-X3-C motif) ligand 1 (*Cx3cl1*), and lymphocyte antigen 6 complex, locus A (*Ly6a*) genes was validated by quantitative real-time-PCR. Because these genes have been previously implicated in osteoporosis, they are potential target genes of C3G action in MC3T3-E1 cells. These results provide molecular level evidence for the therapeutic potential of C3G in the treatment of osteoporosis and other disorders of bone metabolism.

cyanidin-3-O-glucoside, osteogenesis, RNA-sequencing, MC3T3-E1 cells, *Atp6v0c*, *Cx3cl1*, *Ly6a*

## Introduction

Osteoporosis is a disorder of bone metabolism characterized by reduced bone mineral density and a high risk of bone fracture (1). It is a global public health problem (2) that will worsen with the increasing life expectancy of the human population. Osteoblasts and osteoclasts are responsible for bone remodeling, which maintains the integrity of the skeleton (3, 4). Primary cause of osteoporosis is dysfunctional osteoblasts and osteoclasts activity (5). Promoting the proliferation and

differentiation of osteoblasts is an effective way to enhance bone mineral density and prevent osteoporosis (6).

Cyanidin-3-O-glucoside (C3G) is an anthocyanin that is widely distributed in nature (7, 8). C3G evidently has antioxidant and anti-inflammatory effects, therapeutic effects on disease, such as obesity, type 2 diabetes mellitus, and prostate cancer (9, 10), and promotes bone formation and reduces bone loss (11–16). In a study conducted in the United Kingdom, women with high dietary anthocyanin intake had higher bone mineral density (11, 12). In rodents, C3G supplementation can reportedly improve bone quality and reduce bone loss (13, 17, 18), and in other studies it has enhanced osteoblast differentiation and mineralization (19, 20). C3G may be a natural product supporting the prevention and treatment of osteoporosis (21).

To date most studies investigating the molecular etiology of osteoporosis have focused on components of signaling pathways related to bone development such as mitogen-activated protein kinase (MAPK) (22, 23), nuclear factor kappa B (NF- $\kappa$ B) (22), bone morphogenetic protein (BMP) (24), and Wnt (25) pathways. Recent studies have also revealed roles for the chemokine (C-X3-C motif) ligand 1 (CX3CL1)/chemokine (C-X3-C motif) receptor 1 (CX3CR1) signaling axis (26) and glycosylphosphatidylinositol-anchored proteins (27).

Anthocyanins from black rice, which is enriched in C3G (28) and blackberry (29) were shown to affect osteoblast proliferation and differentiation by modulating the expression of target genes including alkaline phosphatase (*Alp*), osteopontin (*Opn*), osterix (*Osx*), and bone gamma-carboxyglutamic acid-containing protein (*Bglap*) (20). C3G increased the mineralization capacity of osteoblasts via the extracellular signal regulated kinase 1/2 (ERK1/2) signaling pathway (19). Several molecular mechanisms of C3G have been investigated in bone cells, but its effects on gene regulation involved in bone formation remain largely unknown.

RNA sequencing (RNA-seq) technology combined with bioinformatics have enabled the large-scale identification of genes associated with normal biological processes and pathogenic processes (30). In current study, gene expression profiles of MC3T3-E1 osteoblast-like cells with and without C3G treatment were investigated by RNA-seq and a functional analyses of differentially expressed genes (DEGs) was conducted to identify those that potentially mediate the protective effects of C3G in osteoporosis.

## Materials and methods

### Chemicals and reagents

C3G with the purity over 98% was purchased from Meilunbio (Dalian, China). TRIzol reagent, primers of quantitative polymerase chain reaction (*qRT-PCR*), a reverse

transcription kit and SYBR Green MasterMix were purchased from Takara Bio (Ostu, Japan). Pancreatin were purchased from Hyclone (Logan, UT, USA). Dimethylsulfoxide (DMSO), phosphate buffered saline (PBS), and other chemicals were purchased from Sigma-Aldrich (Sigma, USA).

### Cell culture

Murine preosteoblast MC3T3-E1 cells obtained from the Cell Bank of the Chinese Academy of Science (Shanghai, China) were cultured in alpha-minimal essential medium supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin (all from Hyclone, Logan, UT, USA) at 37°C and 5% CO<sub>2</sub>. In a previous study, 100  $\mu$ mol/L C3G promoted cell proliferation of MC3T3-E1 cells (19), therefore, 7\*10<sup>5</sup>/ml MC3T3-E1 cells were seeded in 6-well plates in the present study. After the cells had adhere, the cells were synchronized for 24 h using serum-free medium. After completion of the synchronization treatment, the serum-free medium was replaced with complete medium with or without 100  $\mu$ mol/L C3G, and the cells were culture for a further 24 h.

### RNA-seq analysis

Total RNA was extracted from cells using TRIzol reagent and RNA integrity was evaluated *via* agarose gel electrophoresis and spectrophotometry using a NanoDrop ND-1000 instrument (Thermo Fisher Scientific, Waltham, MA, USA). An RNA library was constructed with the KAPA Stranded RNA-seq Library Prep Kit (Illumina, San Diego, CA, USA), and the quality of the library was assessed using 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA). Quantification of the library was performed *via* quantitative real-time PCR (*qRT-PCR*). Sequencing was performed over 150 cycles using the Xten/NovaSeq system (Illumina). Raw RNA-seq data were submitted to NCBI Gene Expression Omnibus (accession number. GSE149731).

### Functional analysis of identified genes

FastQC v0.11.8 was used to analyze the raw RNA-seq data (<http://www.bioinformatics.babraham.ac.uk/projects/fastqc/>) (31). Fragments per kilobase of gene/transcript model per million mapped fragments values for gene and transcript levels were calculated with the Ballgown package (<https://www.bioconductor.org/packages/release/bioc/html/ballgown.html>) of R v2.10.0 software. R was used to generate volcano plots and heatmaps to further analyze gene expression profiles.

Gene Ontology (GO) functional enrichment analysis of DEGs ([www.geneontology.org/](http://www.geneontology.org/)) was performed, and genes

involved in biological process, cellular component, and molecular function GO categories were identified (32, 33). Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis ([www.genome.jp/kegg/](http://www.genome.jp/kegg/)) was conducted to identify signaling pathways associated with the DEGs. All pathways were based on the KEGG database (33).

## Quantitative real-time PCR

RNA was extracted from C3G-treated and untreated MC3T3-E1 cells ( $n = 3$  replicates each) using TRIzol reagent. cDNA was synthesized using a reverse transcription kit, and SYBR Green MasterMix was used for qRT-PCR in a reaction volume of 20  $\mu$ L. qRT-PCR was performed on a real-time PCR machine (ABI 7500, Applied Biosystem, Foster, California, USA). The primer sequences used are shown in Table 1. The glyceraldehyde 3-phosphate dehydrogenase (*Gapdh*) gene was used as the internal control to calculate target gene expression levels *via* the cycle threshold ( $2^{-\Delta\Delta C_t}$ ) method.

## Statistical analysis

Data are presented as mean  $\pm$  standard deviation. Statistical analyses were performed using SPSS v22.0 software (SPSS Inc,

Chicago, IL, USA). Comparisons between two groups were performed with the student's *t*-tests, and  $p < 0.05$  was deemed to indicate statistical significance.

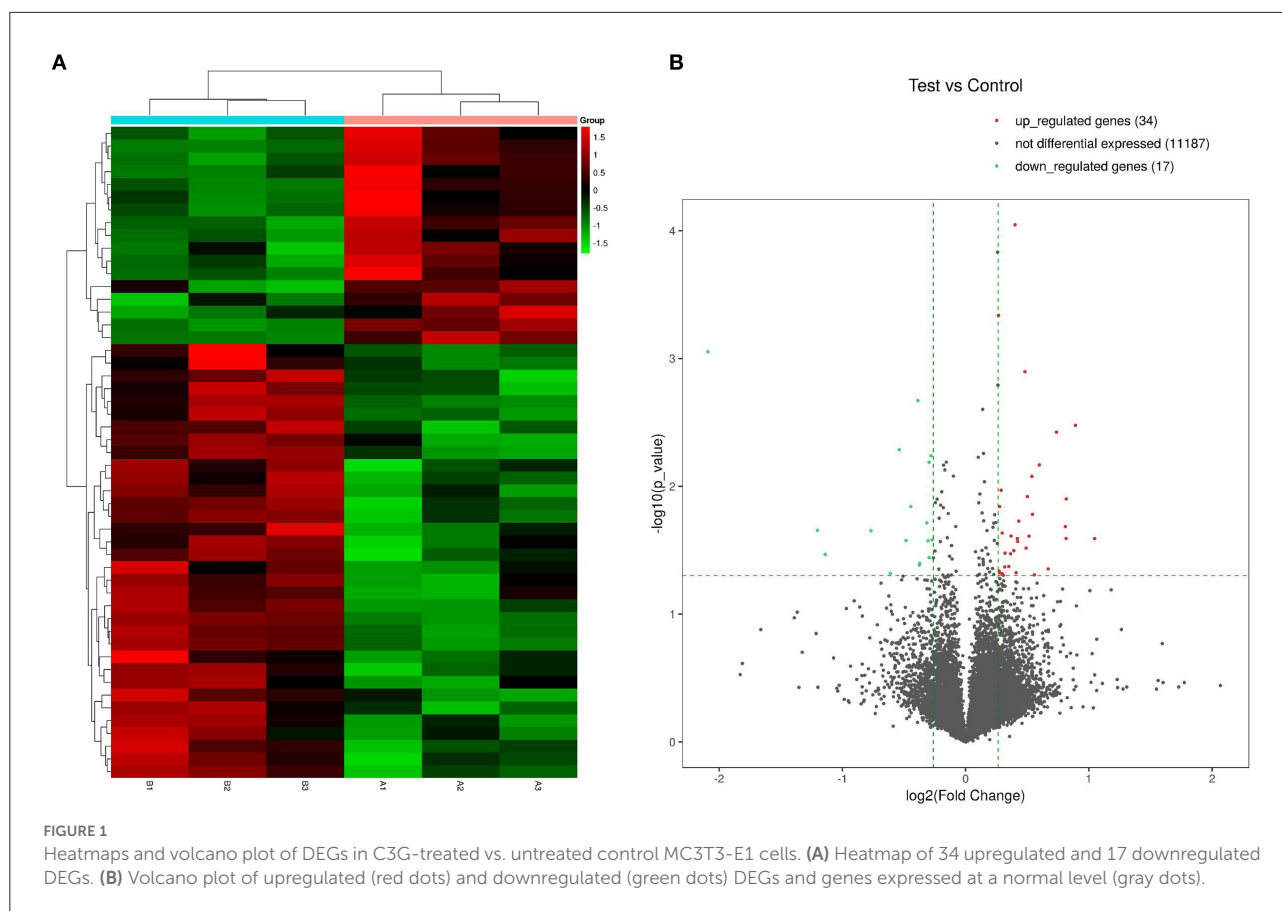

## Results

### Identification of DEGs

Expression profiles of 11,238 genes in C3G-treated and untreated MC3T3-E1 cells were determined by RNA-seq, which yielded 51 DEGs ( $p < 0.05$ , fold change  $\geq 1.2$ ). A heatmap (Figure 1A) and a volcano plot (Figure 1B) were used to represent the abundance of these different transcripts, with expression levels ranging from high (red) to low (green), and there were 34 upregulated and 17 downregulated DEGs. Details of all DEGs are shown in the Supplementary Table 1.

### GO analysis of DEGs

The top 10 biological process terms from the GO analysis of DEGs are presented in Table 2. All biological process terms are listed in Supplementary Table 2. The top three biological process terms for upregulated DEGs were lysosomal lumen acidification (GO:0007042; *Atp6v0c*, *Ccdc115*), regulation of lysosomal lumen pH (GO:0035751; *Atp6v0c*, *Ccdc115*), and

lysosome organization (GO:0007040; *Atp6v0c*, *Ccdc115*). The top three biological process terms for downregulated DEGs were cellular responses to stress (GO:0033554; *Adprhl2*, *Faap24*, *Gm20521*, *Ppp1r15a*, *Rad1*), response to stress (GO:0006950; *Adprhl2*, *Camk2g*, *Cx3cl1*, *Faap24*, *Gm20521*, *Ppp1r15a*, *Rad1*), and vacuolar acidification (GO:0033135; *Ppp1r15a*, *Smad7*) for downregulated DEGs. Several significantly enriched entries were related to cellular responses to stress [GO:0033554; ADP-ribosylhydrolase-like 2 (*Adprhl2*), FA core complex-associated protein 24 (*Faap24*), *Gm20521*, protein phosphatase 1 regulatory subunit 15A (*Ppp1r15a*), *Rad1*], cell-cell junction organization [GO:0045216; *Nectin1*, Mothers against decapentaplegic homolog 7 (*Smad7*)], and cellular responses to DNA damage stimuli (GO:0006974; *Faap24*, *Gm20521*, *Rad1*). With respect to cellular components (Supplementary Table 3), the most significant terms were ATPase for upregulated DEGs (Figures 2A,B) and outer organelle membranes for downregulated DEGs (Figures 2C,D). The most significant terms pertaining to molecular function (Supplementary Table 4) were ubiquitin-like protein ligase binding for upregulated DEGs (Figures 2A,B) and cell adhesion molecule binding for downregulated DEGs (Figures 2C,D). Other significant GO terms included lipoprotein metabolic

process [GO:0042157; lysophospholipase-like 1 (*Lyplal1*), phosphatidylinositol glycan anchor biosynthesis class C (*Pigc*), *Pigk*]; glycosylphosphatidylinositol (GPI) anchor biosynthetic process (GO:0006506; *Pigc*, *Pigk*); glycolipid biosynthetic process (GO:0009247; *Pigc*, *Pigk*); GPI-anchor metabolic process (GO:0006505; *Pigc*, *Pigk*); glycolipid biosynthetic process (GO:0009247; *Pigc*, *Pigk*); glycolipid metabolic process (GO:0006664; *Pigc*, *Pigk*); protein lipidation (GO:0006497; *Pigc*, *Pigk*); and lipoprotein biosynthetic process (GO:0042158; *Pigc*, *Pigk*).

## KEGG pathway analysis of DEGs

KEGG pathway analysis revealed five significantly enriched signaling pathways (Table 3). Four were upregulated including GPI-anchored protein (GPI-AP) biosynthesis signaling pathway (mmu00563; *Pigc*, *Pigk*), tuberculosis [mmu05152; *Atp6v0c*, Fc receptor, IgG, low affinity IV (*Fcgr4*), nuclear transcription factor Y subunit alpha (*Nfya*)], Systemic lupus erythematosus [mmu05322; *Fcgr4*, histone H2B (*Hist1h2bq*)], and Phagosome (mmu04145; *Atp6v0c*, *Fcgr4*) (Figure 3), and one was

and calcium/calmodulin-dependent protein kinase II gamma (*Camk2g*) were expressed at significantly lower levels in C3G-treated MC3T3-E1 cells as determined by qRT-PCR, whereas phosphatidylinositol-4,5-bisphosphate 4-phosphatase (*Tmem55b*), *Gm20521*, *Nkies2*, and testis expressed 2 (*Tex2*) were upregulated. There were no significant differences in *Ppp1r15a* or IQ motif-containing D [*Iqcd*] expression between treated and untreated cells (Figure 4B).

## Discussion

Osteoblasts are specialized fibroblasts that secrete and mineralize bone matrix and play a critical role in osteoporosis. MC3T3-E1 cells can be induced to differentiate into osteoblasts and are used as *in vitro* models to investigate the molecular mechanisms of osteogenesis (34). In current study, RNA-seq of MC3T3-E1 cells treated with the anthocyanin C3G revealed many DEGs as well as GO terms related to lysosomes—e.g., lysosomal lumen acidification, regulation of lysosomal lumen pH, and lysosome organization. This is consistent with previous report that lysosomes play an important role in biogenesis, mineralization, and trafficking of nanovesicles in osteoblasts (35).

GPI metabolism and lipidation were implicated in the effects of C3G on osteoblasts, as revealed by functional

enrichment analyses of DEGs. Phosphorylation of ERK1/2 in osteoblasts promotes the expression of GPI-anchored proteins that maintain cell membrane integrity, which affects osteoblast proliferation (27). Other biological processes including cellular responses to stress (36), cell-to-cell junction organization (19) and cellular responses to DNA damage (37) have been linked to the effects of C3G on osteoblasts. The most significantly enriched KEGG pathways were involved in GPI-anchored protein biosynthesis (upregulated), lupus erythematosus (upregulated), and phagosome (upregulated), and protein processing in endoplasmic reticulum (downregulated). GPI is a ubiquitous glycolipid in eukaryotes (38) that anchors proteins to cell surfaces (39). To date, more than 150 GPI-APs have been identified in mammals (40) including some that are related to bone formation such as ALP, acetylcholinesterase (AChE) (41), and Ly6a (42). The related enzymes PIGC and PIGK play critical roles in GPI synthesis (43). One of the functions of GPI-anchor biosynthesis signaling is to synthesize GPI-Aps. Whether C3G can influence the proliferation and differentiation of osteoblasts by promoting the production of GPI-APs warrants further investigation.

ATP6V0C is a member of the V-ATPase family of enzymes that plays an important role in osteogenesis. Loss of function of V-ATPases results in an osteopetrorickets phenotype due to reduced bone formation (44), and *Atp6v1h*<sup>+/-</sup> mice

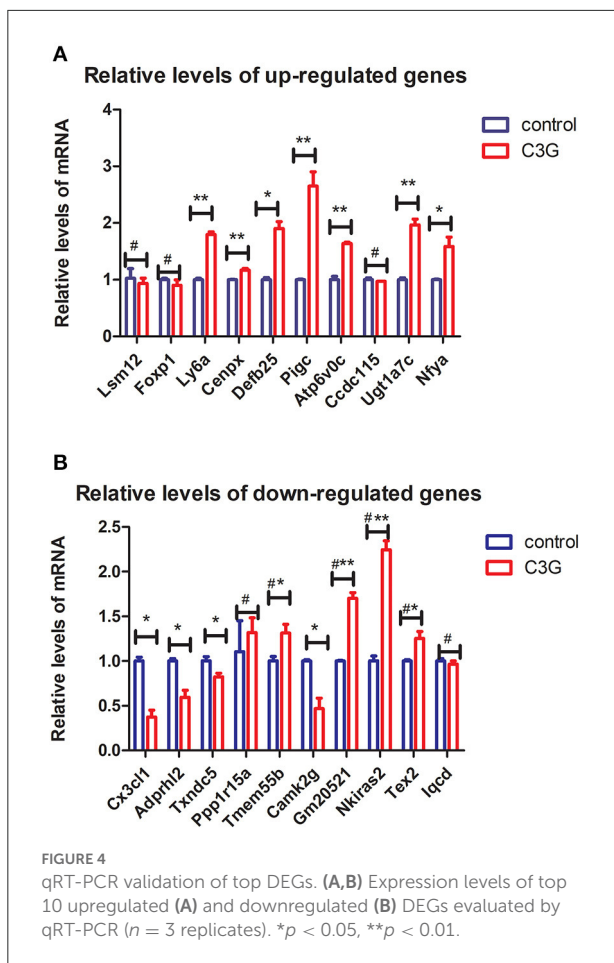

exhibit impaired osteoblast growth as well as abnormal ALP levels (45). V-ATPase deficiency also inhibits osteogenic differentiation and stimulates adipogenic differentiation (46). The CX3CL1/CX3CR1 axis—which has been linked to various diseases including rheumatoid arthritis, spinal cord injury, and osteoarthritis (47)—was identified as a possible target for osteoporosis immunotherapy (48). *Cx3cr1* is expressed in osteoclast precursors, implying that CX3CL1/CX3CR1 signaling can regulate osteoclast differentiation and thus affect the development of osteoporosis (49). *Ly6a* is involved in skull development, fat formation, osteogenesis, and chondrogenesis (50). *Ly6a*-deficient mice exhibit reduced bone formation and osteoclast counts and increased mineralization of trabecular bone, and develop features of consistent with age-related osteoporosis in humans including low bone mass, brittleness, and changes in the mechanical properties of bone (51). Inspired by the results described above, we will perform further studies of investigating the roles of the genes identified in present study, for example via the generation of stable osteoblastic cell lines lacking or overexpressing specific genes. That will

be necessary to clarify the molecular mechanisms underlying osteoblast mineralization.

However, the present study had several limitations. Firstly, we did not examine the expression profile of long non-coding RNAs or microRNAs that may be involved in the effects of C3G on osteogenesis. Secondly, while qRT-PCR validation of RNA-seq results is essential, the methods used differ in terms of sensitivity and specificity, which may explain the differences in DEGs that were observed in our two datasets. In order to identify more sensitive targets, we did not use a higher concentration of C3G but instead selected the minimum concentration that was shown to promote MC3T3-E1 cell proliferation in previous experiments. This may be the reason why *Runx2* and other known osteoporosis-related genes were not identified as DEGs in our RNA-seq analysis (34). In future work, immunoblotting and other experimental approaches should be used to validate biological targets of C3G in MC3T3-E1 cells.

## Conclusion

In summary, we identified 51 genes and 5 signaling pathways (GPI-anchor biosynthesis, tuberculosis, systemic lupus erythematosus, phagosome, and protein processing in the endoplasmic reticulum) via RNA-seq that may mediate the effects of C3G in osteogenesis. Based on their known involvement in osteoporosis, *Atp6v0c*, *Cx3cl1*, and *Ly6a* are the most promising targets of C3G action in osteoblasts. These findings provide evidence for the therapeutic potential of C3G in the treatment of osteoporosis and other disorders of bone metabolism.

## Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary material.

## Author contributions

BZ designed the study. LC, BH, YC, and XW performed the experiments. LC and BH analyzed the data. LC and BZ wrote the manuscript. All authors have read and agreed to the publication of this version of the manuscript.

## Funding

This work was supported by the Liaoning Science and Technology Program (Grant No. 20170540879),

Shenyang Medical College Masters Science and Technology Innovation Fund Project (Grant No. Y20190508), Shenyang Science and Technology Project (Grant No. 19-112-4-024), and Shenyang Medical College Science and Technology Fund (Grant No. 20182045).

## Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
