Plant root systems are essential for the uptake of water and nutrients from soil and are positively correlated to yield in many crops including the sweetpotato, *Ipomoea batatas* (L.) Lam. Here, we isolated and functionally characterized *IbRAP2.4*, a novel nuclear-localized gene encoding the AP2/ERF transcription factor, from sweetpotato. *IbRAP2.4* was responsive to NaCl, PEG8000, ethylene, and Indole 3-acetic acid treatments. As revealed by electrophoretic mobility shift assay and dual luciferase assay, *IbRAP2.4* could bind to both DRE and GCC-box elements and acted as a transcription activator. *IbRAP2.4* overexpression significantly promoted lateral root formation and enhanced the drought tolerance in *Arabidopsis thaliana*, while it inhibited storage root formation in transgenic sweetpotato by comprehensively upregulating lignin biosynthesis pathway genes. Results suggested that *IbRAP2.4* may be a useful potential target for further molecular breeding of high yielding sweetpotato.

Keywords: sweetpotato (*Ipomoea batatas* (L.) Lam), *Arabidopsis*, AP2/ERF, lateral root, storage root, DRE element, GCC-box

INTRODUCTION

Plants sense a wide array of stressors in their environment, including dehydration, which adversely affect their growth and yields. Plant roots uptake water and nutrients, provide anchorage, and monitor environmental conditions in the soil. To ensure plants' survival in changing environments, root systems develop various adaptive traits governed through a complicated mechanism. Therefore, elucidating the molecular mechanisms underlying root architecture can contribute to the improvement of crop yields and stress tolerance.

Plant root systems develop from the root apical meristem initiated during embryogenesis and possibly from multiple non-root-borne adventitious root apical meristems (Motte et al., 2019). Plant root systems exhibit a wide variety of morphologies depending on the species. The model plant, *Arabidopsis thaliana*, has a tap-root system consisting of a central primary root and lateral roots (LRs), whereas several tuber and corm crops such as sweetpotato [*Ipomoea batatas* (L.) Lam.],

develop an adventitious root system that emerges from diverse non-root organs after the embryonic stage (Belehu et al., 2004; Guan et al., 2019; Wei et al., 2019). The sweetpotato root system includes “thick” pigmented storage roots (SRs), “thick” pigmented pencil roots (PRs), and white fibrous roots (FRs) (Wilson and Lowe, 1973; Belehu et al., 2004).

The formation of a plant root system is a strictly controlled developmental process. Accumulating investigations indicated that phytohormones, such as auxins and ethylene, and some key factors involved in hormone signaling, play an essential role in the regulation of root development (Liu et al., 2016; Qin and Huang, 2018; Yoon et al., 2020). The AP2/ERF transcriptional factors, known to play very important roles in hormonal regulation, have been reported to be involved in root architecture regulation in a diverse range of plants. For instance, the degradation of ERF13 induced by auxins could positively regulate LR development in *Arabidopsis* (Lv et al., 2021). *OsERF2*, a transcription factor required for the interplay between ethylene and ABA, negatively regulates primary root growth in rice (Xiao et al., 2016). Moreover, both *OsERF3* and *OsCRL5* could positively regulate the rice response regulators (RRs) of cytokinin signaling during crown root initiation (Kitomi et al., 2011; Zhao et al., 2015). The AP2 DNA-binding domain containing transcription factor family is large group of plant-specific proteins which can be classified into four major subfamilies: AP2 (APETALA2), ERF (Ethylene-Responsive-Element-Binding protein), DREB (Dehydration Responsive Element-Binding), and RAV (Related to ABI3/VP) (Nakano et al., 2006). AP2/ERF transcription factors have also been reported involving in plant (a)biotic stress responses by regulating downstream genes expression *via cis*-acting elements, such as dehydration responsive elements (DRE)/C-repeat element (CRT) and/or GCC box (Lee et al., 2015; Xie et al., 2019). Recently, several genes belonging to the AP2/ERF transcription factor family have been isolated from sweetpotato (Kim Y. H. et al., 2012; Li et al., 2019; Yu et al., 2020). However, none is reported to regulate root development.

Sweetpotato is a food crop cultivated in all tropical and subtropical regions, particularly in Asia, Africa, and the Pacific (El Sheikha and Ray, 2017). SRs constitute the most economically important agronomic trait in sweetpotato production; therefore, understanding the mechanisms controlling root development is crucial for high yields breeding of sweetpotato. To reveal how AP2/ERF transcription factors affected sweetpotato root development, we isolated and functionally characterized a novel nuclear-localized AP2/ERF transcription factor, *IbRAP2.4*, in sweetpotato. *IbRAP2.4* could directly bind with the DRE and GCC-box elements where it acted as a transcription activator. *IbRAP2.4* overexpression significantly promoted LR formation and enhanced drought tolerance in *Arabidopsis thaliana*, whereas it simultaneously and substantially inhibited the formation of SRs but induced PRs in sweetpotato. The expression levels of *cinnamoyl-CoA reductase (CCR)*, *caffeic acid/5-hydroxyferulic acid O-methyltransferase (COMT)*, and *caffeoyl-CoA O-methyltransferase (CCoAOMT)* genes involved with lignin biosynthesis were increased in *IbRAP2.4*-overexpressing transgenic sweetpotato. Functional analysis of

IbRAP2.4 regarding the regulation of root architecture provides a framework for the future breeding of high yielding sweetpotato.

MATERIALS AND METHODS

Plants Materials and Growth Conditions

Sweetpotato cultivar Sushu 16 (bred by Jiangsu Academy of Agricultural Sciences) and Xushu 29 (bred by Jiangsu Xuzhou Sweetpotato Research Center), and *Arabidopsis thaliana* ecotype Columbia-o (Col-o) were used in this study. Xushu 29 and Col-o plants were used as the wild-type (WT) to generate transgenic lines. Sweetpotato plants were propagated by cuttings (tips: top 10 cm) and grown in a growth chamber under a 16 h light/8 h dark photoperiod at 25°C. The seeds of *Arabidopsis* were surface sterilized, sown on 1/2 Murashige and Skoog (MS) medium, and then grown in a growth chamber under a 16 h light/8 h dark photoperiod at 22°C. Untransformed and transgenic sweetpotato plants were transplanted into the field in mid-May for evaluation of the phenotype in Nanjing, Jiangsu. For gene expression pattern analysis, sweetpotato seedlings were cultured in 1/2 Hoagland nutrient solution for 10 d and subsequently subjected to stress treatments by supplementing with 150 mM NaCl (salt stress), 20% polyethylene glycol (PEG) 8,000 (drought stress), 100 μM ethylene, and 100 μM indole-3-acetic acid (IAA), respectively. The fourth fully expanded leaf from the top was sampled at 0, 3, 6, 12, 24, 48 h after treatment. Plant tissues (leaves, stems, FRs, PRs, and SRs) collected from the 10-week-old sweetpotato plants under normal growth conditions were used for tissue-specific expression analysis. For drought stress treatment of *Arabidopsis*, after being sown in pots and regularly watered for 2 weeks, transgenic plants and WT were subjected to withholding of watering for 7 days followed by 1 day of recommenced watering.

Isolation and Analysis of IbRAP2.4

The *IbRAP2.4* gene was predicted by the Sushu 16 transcriptome database, and isolated from the cDNAs of Sushu 16 by using sequence-specific primers (**Supplementary Table 1**). The PCR products were then fused into the pEASY-Blunt cloning vector (TransGen, Beijing, China) for sequencing confirmed with five independent clones.

The conserved domain of the IbRAP2.4 protein was scanned by CD-search.¹ Homologous sequences of IbRAP2.4 were identified using the BLASTp search program of the National Center for Biotechnology Information.² Molecular phylogenetic analysis was constructed using the UPGMA method and MEGA 6.³ Sequence alignment was conducted with BioEdit.⁴ A 2.0 kb-length promoter region of *IbRAP2.4* exported from the sweetpotato genome database⁵ were analyzed by the PlantCARE.⁶

Transcriptional Activation Assay of IbRAP2.4

The full-length *IbRAP2.4* coding sequence (CDS) was inserted into the pGBKT7 vector to produce the fusion construct pGBKT7-IbRAP2.4 (Primer pair RAPHY-F/R, **Supplementary Table 1**). The generated plasmid pGBKT7-IbRAP2.4 and the empty pGBKT7 vector (negative control) were transformed into the yeast (*Saccharomyces cerevisiae*) strain AH109 separately. Yeast cells grown on SD/-Trp and SD/-Trp/-His/-Ade plates were incubated at 30°C for 3–5 days.

Subcellular Localization

Subcellular localization analysis of IbRAP2.4 was determined in 3-week-old tobacco (*Nicotiana benthamiana*) leaves and conducted as described previously (Waadt and Kudla, 2008). The coding sequence of *IbRAP2.4* was amplified and constructed into the transient expression vector pCAMBIA1305-GFP (primer pair RAPG-F/R, **Supplementary Table 1**). The construct was transformed into *Agrobacterium tumefaciens* strain GV3101 and then used to infiltrate *N. benthamiana* leaves. The infiltrated *N. benthamiana* were maintained in a growth chamber under a 16 h light/8 h dark photoperiod at 25°C for 2 days. Samples with 4',6'-diamidino-2-phenylindole (DAPI) staining were collected for detection of fluorescent signal with a Leica TCS SP5 confocal laser scanning microscope.

Gene Expression Level Analysis

Total RNA of samples was isolated by using RNAPrep Pure Plant kit (Polysaccharides and Polyphenolics-rich) (Tiangen, Beijing, China) and then used to synthesize the first-strand cDNA with FastKing gDNA Dispelling RT SuperMix kit (Tiangen, Beijing, China). Primer pairs specific to tested genes were designed using the GenScript online tool⁷ and then used to quantify the expression level by quantitative real-time PCR (qRT-PCR) amplification (**Supplementary Table 1**). qRT-PCR was performed using a SYBR® Premix Ex Taq™ kit (TaKaRa) on an ABI prism 7,900 Real-Time PCR System. The sweetpotato *Tublin* gene was used as a reference and relative changes of gene expression was analyzed by the $2^{-\Delta\Delta CT}$ method (Livak and Schmittgen, 2001).

Vector Construction and Plant Transformation

The full length sequence of *IbRAP2.4* was cloned into the plant expression vector pCAMBIA1305 behind the *CaMV35S* promoter to generate *CaMV35S:IbRAP2.4* construct (Primer pair ORAP-F/R, **Supplementary Table 1**). *CaMV35S:IbRAP2.4* plasmid was transferred into *Agrobacterium tumefaciens* EHA105 and introduced into Col-o and Xushu 29, respectively, as previously described (Clough and Bent, 1998; Kim S. H. et al., 2012). For *Arabidopsis*, the first generation (T_0) seeds were germinated on 1/2 MS medium with 40 mg L⁻¹ hygromycin for screening. For sweetpotato, the transformed

calli were selected on MS medium containing 400 mg L⁻¹ cefotaxime and 25 mg L⁻¹ hygromycin. All transgenic lines were confirmed by PCR amplification of hygromycin and qRT-PCR with specific primers (Primer pair hyg-F/R, **Supplementary Table 1**).

Purification of GST-IbRAP2.4 Fusion Protein and Electrophoretic Mobility Shift Assay

The GST:IbRAP2.4 plasmids was transformed to *E. coli* strain BL21 (DE3) and the recombinant protein was purified by affinity chromatography using a Glutathione Sepharose 4B column (GE Healthcare, Uppsala, Sweden) according to the manufacturer's protocols. The DRE (5'-TTGATACTACCGACATGAGTTGATACTACCGACATGAGTT-3') and GCC-box (5'-TTCATAAGAGCCGCCACTCATAAGAGCCGCCACT-3') sequences used as probes were according to the findings of Lin et al. (2008). To prepare probes, oligonucleotide sets were annealed by boiling for 5 min and then labeled with [γ -³²P]-ATP by adding T4 Polynucleotide Kinase (Promega, Madison, WI, United States). A 30 μ L binding reactions were performed by the addition of labeled probe (0.5 μ g) and purified GST-IbRAP2.4 or GST protein (10 μ g) into the binding buffer (200 mM HEPES, 50 mM KCl, 5 mM DTT, 1 mM EDTA, and 20 pmol of poly dI-dC) and then allowed to proceed at room temperature for 30 min. Afterward, the sample was electrophoresed on an 8% native polyacrylamide gel and visualized by autoradiography. Competition experiments were carried out by incubating increasing amounts of unlabeled competitor probe with purified GST-IbRAP2.4 fusion protein before the addition of labeled probes.

Assay of Luciferase Activity and Chlorophyll Content

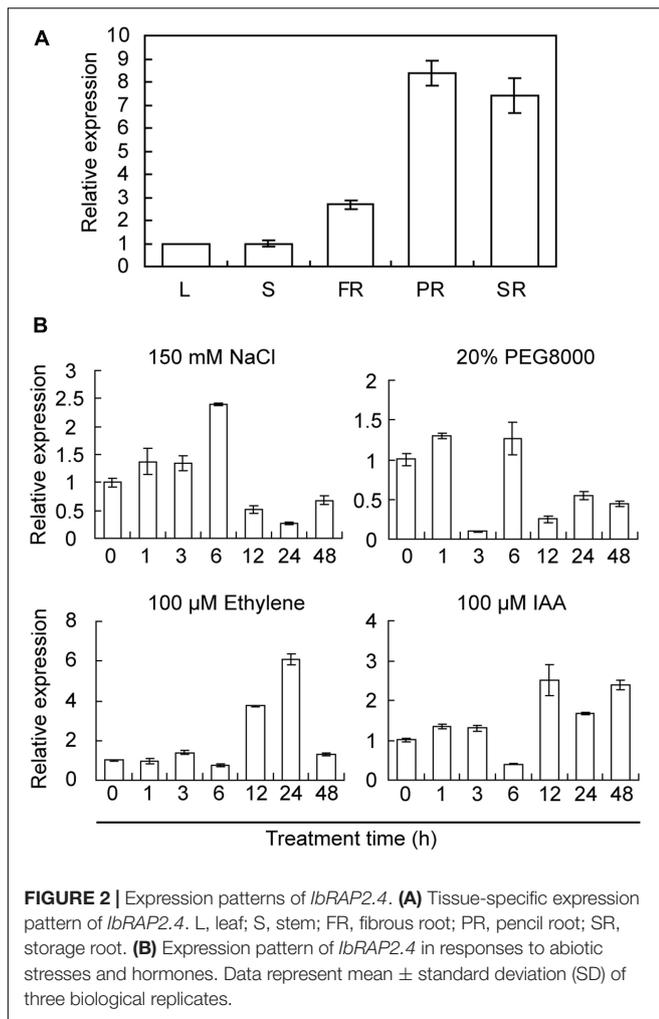

The 4 \times DRE and 3 \times GCC fragments were inserted to pGreen 0800-Luc vector, respectively. The reporter (4 \times DRE-Luc/3 \times GCC-Luc) and effector (35S:IbRAP2.4) (or empty vector) were co-transformed into *Arabidopsis* protoplasts via a PEG transformation method, performed as previously described (Iwata et al., 2011). Luciferase activities were measured with the Dual-Luciferase Reporter Assay System.⁸ To measure the chlorophyll content in transgenic *Arabidopsis*, the fourth fully expanded leaves from the top of transgenic lines and WT plants were collected for detection using a portable chlorophyll meter (SPAD-502, Konica Minolta, Japan).

Statistical Analysis

Three biological replicates were performed for all experiments. Difference analysis of data presented as the mean \pm standard deviation (SD) was performed with Student's t-test (two-tailed analysis) using SPSS, version 20.0 (IBM Corporation, Armonk, NY, United States). Significance levels at $P < 0.05$, and $P < 0.01$ are indicated by * and **, respectively.

⁸<http://www.promega.com>

hormones, the expression of *IbRAP2.4* was detected in Sushu 16 seedlings under different treatments. As shown in **Figure 2B**, the expression of *IbRAP2.4* was upregulated by NaCl, beginning to increase at 1 h, peaking at 6 h, and then decreasing. Under PEG8000 stress, the expression of *IbRAP2.4* was slightly induced at only 1 and 6 h, but was significantly decreased at 3 h and after 12 h. When treated with ethylene, transcription of *IbRAP2.4* was upregulated at 12 h, reached its maximum at 24 h and decreased at 48 h. For IAA treatment, after a slight increment in the first 3 h, the expression of *IbRAP2.4* decreased immediately at 6 h but was induced dramatically over the following 12 h. Taken together, these results suggest that *IbRAP2.4* is induced by salinity, dehydration, ethylene, and IAA.

IbRAP2.4 Binds to the Dehydration Responsive Elements and GCC-Box Elements and Acts as a Transcriptional Activator

It has been reported that amounts of AP2-domain containing proteins can bind to the dehydration responsive element (DRE,

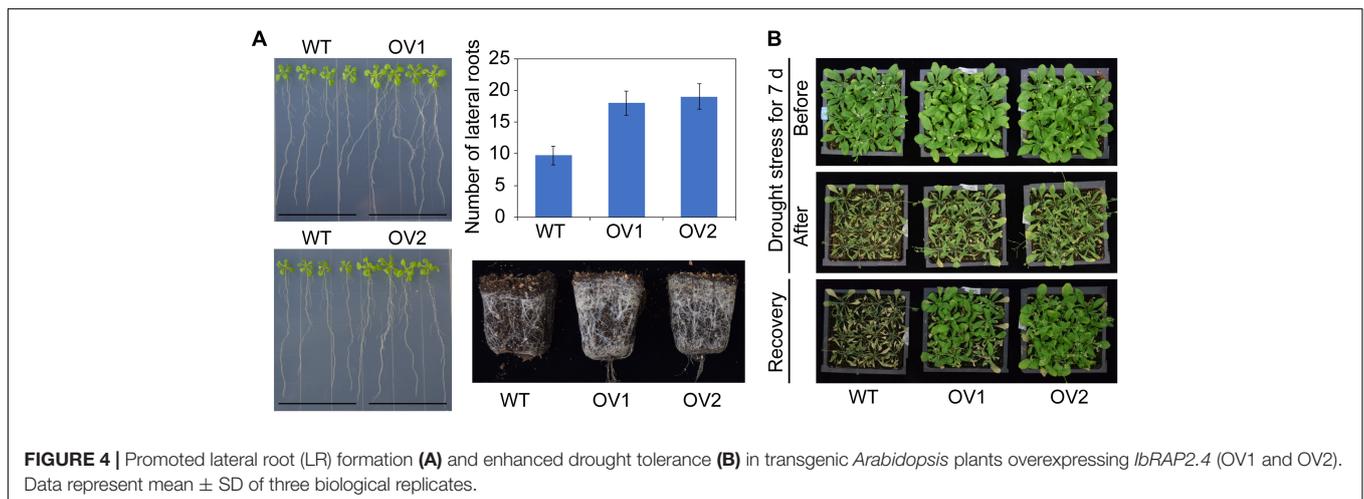

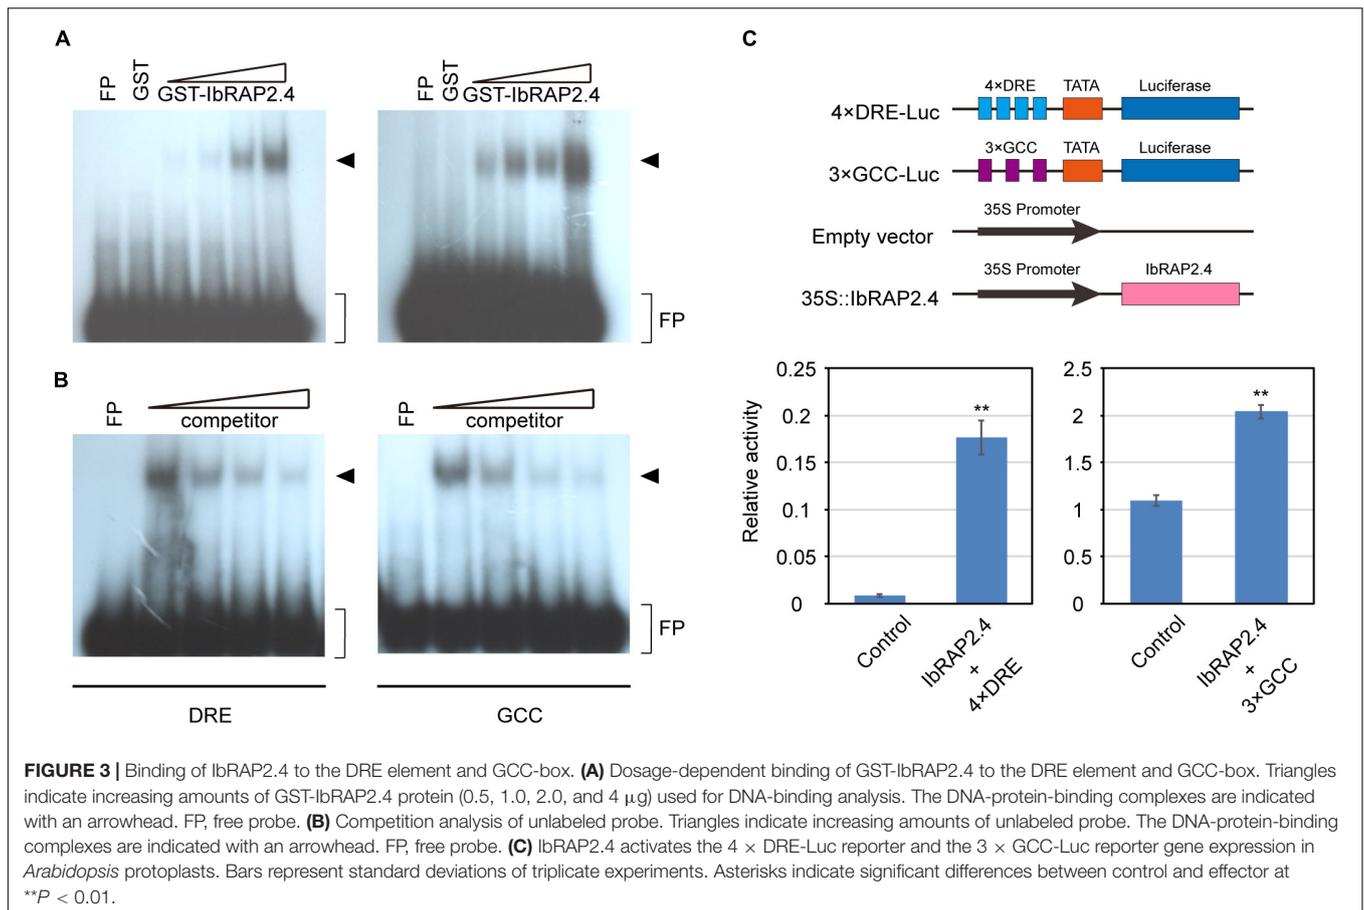

core sequence TACCGACAT) or the ethylene-responsive GCC-box (core sequence AGCCGCC) (Lin et al., 2008). To directly test the DNA-binding activity of IbRAP2.4, we performed an electrophoretic mobility shift assay (EMSA) using recombinant GST-IbRAP2.4 fusion protein and labeled DRE or GCC-box element. The results showed that GST-IbRAP2.4 fusion protein, but not GST alone, can bind with both the DRE and GCC-box in a dosage-dependent manner (**Figure 3A**). Excess amounts of unlabeled probes can effectively reduce or abolish the binding of GST-IbRAP2.4 to the labeled DRE or GCC-box element (**Figure 3B**). These results indicate that IbRAP2.4 can specifically bind to both the DRE and GCC-box element *in vitro*.

To determine whether IbRAP2.4 acts as a transcriptional activator or repressor, its transcriptional activity was examined by dual luciferase assay (Dual-Luc) in *Arabidopsis thaliana* protoplasts. The reporter plasmid contained the luciferase (*LUC*) gene fused to four copies of the DRE element or three copies of the GCC-box element, and the effector plasmid contained full-length CDS of *IbRAP2.4* with double copies of the 35S promoter (**Figure 3C**). The luciferase activity showed a more than two-fold increment in the presence of IbRAP2.4 protein, compared to that of the control, indicating strong activator activity of *IbRAP2.4* in transcriptional regulation of DRE-containing and GCC-box-containing gene expression in plant cells.

Overexpression of IbRAP2.4 Promoted Lateral Root Formation and Enhanced Drought Tolerance in Transgenic *Arabidopsis thaliana*

To further characterize the function of *IbRAP2.4* in plants, we firstly generated transgenic *Arabidopsis thaliana* that overexpressed *IbRAP2.4*. Two independent T3 homozygous lines (OV1 and OV2) of *Arabidopsis* overexpressing *IbRAP2.4* (data not shown) with obvious phenotypes were selected as representatives. Compared with WT, the LR formation of *Arabidopsis* transgenic plants was affected by *IbRAP2.4* overexpression (**Figure 4A**). A notably promoted LR formation was observed in OV lines at day 12 after sowing, and the post-harvest total root production in OV lines was obviously increased owing to accelerated LR growth. In addition, OV plants displayed enlarged rosette leaves, both in length and width. The biomass of *IbRAP2.4* overexpressed plants was higher than that of the control. In contrast, overexpression of *IbRAP2.4* caused a reduction in chlorophyll content (**Supplementary Figure 3**).

To reveal whether *IbRAP2.4* contributed to the tolerance of drought stress, both the transgenic lines and WT grown in pots for 2 weeks were treated with drought. No obvious difference was observed between WT and OVs under normal conditions, whereas the WT plants exhibited increased sensitivity to drought stress compared with the overexpressed-*IbRAP2.4* transgenic lines (**Figure 4B**). After re-watering for 1 day, plants of transgenic *Arabidopsis* lines OV1 and OV2 only displayed slight wilting and successfully recovered, while most of the WT nearly died with their leaves turned yellow and were shrunken in size. All

these results illustrate that overexpressed *IbRAP2.4* promoted LR formation and enhanced drought tolerance in *Arabidopsis*.

Overexpression of *IbRAP2.4* Affected Root Formation in Sweetpotato

To confirm the role of *IbRAP2.4* in sweetpotato, it was transformed into Xushu 29, a variety known to be suitable for

transformation, to generate overexpression lines. A total of 12 transgenic lines were obtained and confirmed by PCR (data not shown) and qRT-PCR (**Figure 5A**). Three transgenic lines (L1 to L3) exhibiting high *IbRAP2.4* expression were selected as representatives (OE1 to OE3) for further characterization. The transgenic lines and WT plants showed no differences in response to drought stress (data not shown). However, after the plants were harvested from the field, obvious phenotypic

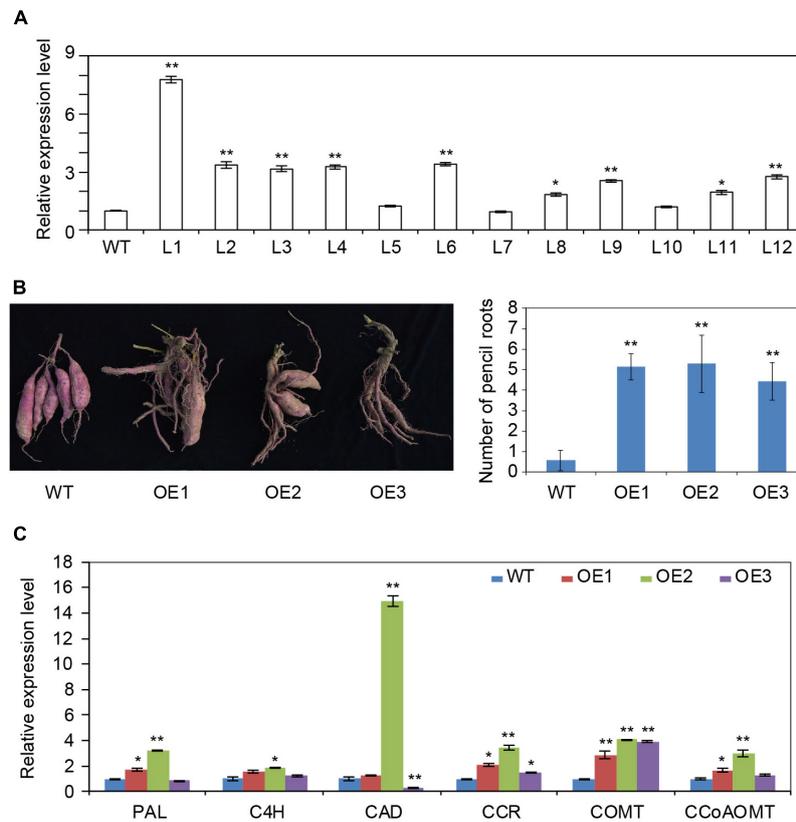

FIGURE 5 | Overexpression of *IbRAP2.4* in sweetpotato. **(A)** qRT-PCR analysis of sweetpotato transgenic lines overexpressing *IbRAP2.4* (L1 to L12). **(B)** Reduced number of storage roots (SRs) but increased number of pencil roots (PRs) produced by representative transgenic lines (OE1 to OE3). **(C)** Expression of genes involved in lignin biosynthesis. Data represent mean \pm SD of three biological replicates. The asterisks represent significant differences from the WT at * $P < 0.05$ or ** $P < 0.01$.

changes were observed in the mature storage roots in *IbRAP2.4* overexpression transgenic lines compared to the WT (**Figure 5B** and **Supplementary Figure 4**). Under field conditions, WT produced 3–5 storage roots per plant, whereas the number of SRs in OE lines was notably reduced. In contrast, more PRs were produced by OE lines, ranging from 4.43 (in L3) to 5.29 (in L2); this was far superior to the WT (0.57).

As PRs are a type of lignified thick root, it was speculated that lignin biosynthesis in transgenic sweetpotato might be impacted by overexpressing *IbRAP2.4*. The expression of key enzyme genes involved in lignin biosynthesis, including *phenylalanine ammonia-lyase* (PAL), *cinnamate 4-hydroxylase* (C4H), *cinnamyl alcohol dehydrogenase* (CAD), *cinnamoyl-CoA reductase* (CCR), *caffeic acid/5-hydroxyferulic acid O-methyltransferase* (COMT), and *caffeoyl-CoA O-methyltransferase* (CCoAOMT), was analyzed by qRT-PCR using 5-week-old seedlings (**Figure 5C**). Compared to the WT, the three OE lines showed 2.88- to 4.12-fold changes in the expression of COMT. A slight up-regulation with 1.53- to 3.43-fold changes was also observed in the expression of CCR in transgenic lines. These results indicate that overexpression of *IbRAP2.4* inhibited SR formation by activating the expression of genes involved in the lignin biosynthesis pathway.

DISCUSSION

We identified the *IbRAP2.4* gene as a novel regulator of root development. The *IbRAP2.4* protein shares high similarity with *Arabidopsis* RAP2.4 which belongs to the DREB subfamily of AP2/ERF family (**Figure 1**). Many members of the AP2/ERF family are known to bind to either the DRE element or the ethylene-responsive GCC-box, while others bind to both of the two *cis*-elements (Phukan et al., 2017; Xie et al., 2019). In accordance with *Arabidopsis* RAP2.4 (Lin et al., 2008), *IbRAP2.4* can bind to both the DRE and GCC-box *cis*-elements, and acts as a transcription activator (**Figure 3**). DREBs have been extensively examined under abiotic stress, where they respond to and positively regulated drought, cold, salt, and heat tolerance by regulating stress-responsive genes (Xie et al., 2019). Drought- and salt- inducible *Arabidopsis* RAP2.4 is reported to regulate multiple developmental processes and drought stress tolerance (Lin et al., 2008; Yang et al., 2020). In this study, *IbRAP2.4* expression was highly detected in sweetpotato roots (**Figure 2A**), and induced by treatments of salinity, dehydration, ethylene, and IAA (**Figure 2B**). In addition to the enhanced drought tolerance in *IbRAP2.4* OVs, overexpression of *IbRAP2.4* in *Arabidopsis* and sweetpotato displayed promoted LR formation and increased

PRs respectively (Figures 4, 5), illustrating the regulatory role of *IbRAP2.4* in plant root development.

Lateral roots in *IbRAP2.4*-overexpression *Arabidopsis* lines exhibited promoted formation. The whole process of LR development in *Arabidopsis* has been well established and auxins play essential roles in each developmental phase (Du and Scheres, 2018). AP2/ERF transcription factors were found to be involved in auxin-regulated LR development. The auxin-regulated PUCHI gene, encoding an AP2/ERF transcription factor, is required for a coordinated pattern of cell division during LR formation in *Arabidopsis* (Hirota et al., 2007). ERF109-mediated cross-talk of JA signaling and auxins regulate LR formation by directly activating auxin biosynthesis genes (Cai et al., 2014). Recently, Lv et al. (2021) reported that *ERF13* acts as a negative regulator of LR development that is degraded upon auxin perception through an MPK14-dependent pathway. Although the expression of *IbRAP2.4* in sweetpotato was induced by the active auxin IAA (Figure 2B), further confirmation is needed as to whether *IbRAP2.4*-controlled LR development depends on an auxin-regulated pathway.

Arabidopsis lines expressing *CaMV35S:IbRAP2.4* showed improved drought tolerance as compared to WT (Figure 4B). Previous studies have implicated several *Arabidopsis* AP2/ERF family genes in drought stress tolerance but with different mechanisms. For instance, transgenic alfalfa (*Medicago sativa*) overexpressing *WXP1* with increased cuticular wax accumulation on leaf surfaces shows enhanced drought tolerance (Zhang et al., 2005, 2007). Whereas overexpression of *OsERF71* changes the root structure of plants through modification of its cell wall, thereby enhancing rice tolerance to drought stress (Lee et al., 2016). A direct correlation between root architecture and resistance to water deficit has been shown in many crop plants. Root-specific overexpression of three *OsNACs* (*OsNAC5*, *OsNAC59*, and *OsNAC510*) notably enlarges roots, which in turn enhances drought tolerance (Jeong et al., 2010, 2013; Redillas et al., 2012). In addition, overexpression of *DEEPER ROOTING1* confers a drought avoidance capacity by altering rice root architecture (Uga et al., 2013). LRs increase the contact area of roots with soil particles and thereby aid water and nutrient absorption from the soil (Ahmed et al., 2016). A previous study also elucidates that higher LR density can potentially enhance drought tolerance for plants (Placido et al., 2020). Therefore, we speculated that the enhanced drought tolerance in overexpressed *IbRAP2.4* transgenic *Arabidopsis* may be a result of its promoted LR development. Furthermore, *IbRAP2.4*-overexpression sweetpotato lines did not show a significant phenotype for drought tolerance, which may be explained by the different regulatory mechanisms of root system formation between *Arabidopsis* and sweetpotato.

Sweetpotato yield and quality are dependent upon SR development during plant growth. Therefore, much of the research on sweetpotato focuses on the mechanisms underlying SR formation and development. The sweetpotato plant initially produces colorless FRs, with some of these subsequently acquiring pigmentation and undergoing “thickening” growth to form PRs that ultimately develop into SRs. Recently, a number of genes related to SR formation have been identified in

sweetpotato, such as: *SRD1*, which is essential for the initiation and development of tuberous roots by influencing auxin synthesis (Noh et al., 2010); expansion gene *IbEXPI*, which affects the weight and number of SRs (Noh et al., 2013); and *IbNAC083*, a core regulator of SR swelling initiation (He et al., 2021). Results of overexpressed *IbRAP2.4* transgenic sweetpotato suggested a role for the AP2/ERF transcription factor in SR development (Figure 5 and Supplementary Figure 4). Lignification of the middle column inhibits the conversion of adventitious roots to SRs (Belehu et al., 2004), and transcriptomic analysis validated the down-regulation of lignin biosynthesis and up-regulation of starch biosynthesis related genes at an early stage of SR formation (Firon et al., 2013). Consistent with these conclusions, inhibited SR formation in *IbRAP2.4*-overexpression sweetpotato lines was caused by elevated root lignification levels with activated expression of genes involved in the lignin biosynthesis pathway.

The AP2/ERF transcription factors were reported to be involved in lignin biosynthesis regulation by directly binding to DRE element or GCC-boxes in the promoters of the lignin biosynthetic genes. *OsERF71* was found to control lignin biosynthesis in roots by directly binding to the promoter of *OsCCR1*, which contains a GCC core cis-element (Lee et al., 2016). *EjERF39* could transactivate the promoter of the lignin biosynthetic gene *Ej4CL1* by recognizing the DRE element (Zhang et al., 2020). In the current study, an enhanced expression level of lignin biosynthetic genes was observed in OE lines, especially *CCR* and *COMT* (Figure 5C). The bioinformatic analysis of the *cis* elements in the promoter region of *CCR* revealed two DRE core elements to be present at the promoter of *CCR* (Supplementary Figure 2), suggesting the possibility that *IbRAP2.4* promoted lignin biosynthesis during SR formation by recognizing and directly binding to the DRE element within the promoter of *CCR*.
