## About Frontiers

Frontiers is more than just an open access publisher of scholarly articles: it is a pioneering approach to the world of academia, radically improving the way scholarly research is managed. The grand vision of Frontiers is a world where all people have an equal opportunity to seek, share and generate knowledge. Frontiers provides immediate and permanent online open access to all its publications, but this alone is not enough to realize our grand goals.

## Frontiers journal series

The Frontiers journal series is a multi-tier and interdisciplinary set of open-access, online journals, promising a paradigm shift from the current review, selection and dissemination processes in academic publishing. All Frontiers journals are driven by researchers for researchers; therefore, they constitute a service to the scholarly community. At the same time, the *Frontiers journal series* operates on a revolutionary invention, the tiered publishing system, initially addressing specific communities of scholars, and gradually climbing up to broader public understanding, thus serving the interests of the lay society, too.

## Dedication to quality

Each Frontiers article is a landmark of the highest quality, thanks to genuinely collaborative interactions between authors and review editors, who include some of the world's best academicians. Research must be certified by peers before entering a stream of knowledge that may eventually reach the public - and shape society; therefore, Frontiers only applies the most rigorous and unbiased reviews. Frontiers revolutionizes research publishing by freely delivering the most outstanding research, evaluated with no bias from both the academic and social point of view. By applying the most advanced information technologies, Frontiers is catapulting scholarly publishing into a new generation.

## What are Frontiers Research Topics?

Frontiers Research Topics are very popular trademarks of the *Frontiers journals series*: they are collections of at least ten articles, all centered on a particular subject. With their unique mix of varied contributions from Original Research to Review Articles, Frontiers Research Topics unify the most influential researchers, the latest key findings and historical advances in a hot research area.

Find out more on how to host your own Frontiers Research Topic or contribute to one as an author by contacting the Frontiers editorial office: [frontiersin.org/about/contact](https://frontiersin.org/about/contact)

## Editorial on the Research Topic

### Cardio-oncology: mechanisms and therapeutics

Cancer and cardiovascular disease share similar risk factors and are both prevalent among aging populations. Individuals with a history of cancer are exposed to a 2–3 times higher chance of getting acute coronary syndrome (ACS), which can persist for up to 10 years after a cancer diagnosis (1). Cancer patients with cardiovascular comorbidity have worse survival rates than cancer patients alone (2, 3). Reciprocally, myocardial infarction also hastens the spread of cancer and worsens the prognosis of cancer patients (4, 5). In this regard, understanding the interaction between cancer and cardiovascular disease may help avoid tackling diseases in a siloed approach and improve the outcome of these patients with comorbidity.

In addition, novel cancer therapies have tremendously improved the survival of cancer patients but also increased treatment-related side effects (6, 7). Cardiovascular toxicities are the most common adverse effects, threatening survival and impairing life quality of the cancer survivors (8). Cancer survivors' early morbidity and death are largely affected by these side effects (9). Understanding the mechanisms underlying anticancer treatment-induced cardiotoxicity can help develop novel therapeutics to avoid or lessen it.

The purpose of this research topic is to bring together a collection of works that provide novel insights into interactions between cancer and cardiovascular disease as well as mechanisms and therapeutics of anticancer treatment-induced cardiotoxicity. All contributions to this research topic concentrate on one or more of the above-mentioned study topics and several studies referenced below are representative.

## N<sup>6</sup>-Methyladenosine in cyclophosphamide-induced cardiotoxicity

The RNA epitranscriptomics represented by N<sup>6</sup>-Methyladenosine (m<sup>6</sup>A) are increasingly recognized to play important roles in physiology and disease (10). Cyclophosphamide is frequently prescribed to treat various types of cancers and autoimmune conditions. Accumulated doses of this drug may result in fatal hemorrhagic myocarditis (11). Zhu et al. demonstrated that the pathogenesis of cyclophosphamide-induced cardiotoxicity involves the downregulation of Junctophilin 2 (JPH2) levels. The proper structure and function of junctophilin-2 (JPH2) are recognized to be indispensable for proper excitation-contraction coupling in cardiomyocytes (12). The increased m<sup>6</sup>A level of JPH2 mRNA induced by N<sup>6</sup>-Methyladenosine writer METTL3 decreased its expression levels, and consequently

dysregulated calcium signaling in cardiomyocytes. These results identified a novel epitranscriptomic mechanism regulating JPH2 expression and offers novel approaches to the management of cyclophosphamide-induced cardiotoxicity.

## miR-194-5p contributes to doxorubicin-induced cardiotoxicity

Doxorubicin is a popular anticancer agent but is well-known for its cardiotoxicity in many patients. The mechanisms underlying doxorubicin (DOX)-induced cardiotoxicity remain not fully understood. miRNAs are widely involved in the progression of various cardiovascular diseases (13). Fa et al. revealed the important role of miR-194-5p in the pathogenesis of DOX-induced cardiotoxicity. MiR-194-5p silencing reduced doxorubicin (DOX)-induced cardiotoxicity *in vitro* and *in vivo* by upregulating PAK2 and XBP1s. Overexpression of PAK2 or XBP1s reduced miR-194-5p- exacerbated cardiomyocyte apoptosis. This work was the first to identify a novel pathogenic miR-194-5p/PAK2/XBP1s axis in DOX-induced cardiotoxicity, hence proposing a potential target for the prevention and treatment of DOX-induced cardiotoxicity.

## NT-proBNP can predict cardiovascular symptoms caused by Pd-1 inhibitor therapy

In recent years, immunotherapy has achieved great success in cancer treatment. Unfortunately, cardiotoxicity appears to have emerged as an unneglectable issue recently (14). The work by Peng et al. suggested that NT-proBNP could predict cardiovascular symptoms in individuals with myocardial damage following PD-1 inhibitor therapy, while highly sensitive troponin T (hsTnT) is the best cardiac biomarker for mortality prediction in symptomatic patients. This study may help medics to perform risk stratification for patients at an earlier time and to implement effective interventions at the early stage of PD-1 inhibitor-related myocarditis.

## A large-scale observation in cancer patients suffering from infective endocarditis

Infective endocarditis (IE) occurs more frequently in cancer patients as compared with the general population (15). IE was predominantly community-acquired (74.8%) in cancer patients, according to Cosyns et al. The most common complications were acute renal failure (25.9%), embolic events (21.7%), and congestive heart failure (18.1%). This is a sizable observational cohort of IE patients with cancer. It sheds light on current IE cancer patient profiles, treatment, and outcomes. Considering the lack of randomized and large-scale observational data on IE cancer patients, this registry provides a unique viewpoint on IE management in cancer patients.

## D-Dimer is a predictive factor for cancer therapeutics-related cardiac dysfunction

Improved early detection methods have allowed a larger number of cancer patients with cancer therapeutics-related cardiac dysfunction (CTRCD) to live longer (16). Oikawa et al. consecutively enrolled 169 patients who planned to receive cardiotoxic chemotherapy for 12 months of follow-up and found that the incidence of CTRCD was greater in the high D-dimer group than in the low D-dimer group (16.2 vs. 4.5%,  $p = 0.0146$ ). High D-dimer levels at baseline were an independent predictor of the development of CTRCD, according to multivariable logistic regression analysis [odds ratio 3.93, 95% CI (1.00–15.82),  $p = 0.047$ ]. It is suggested that D-dimer may be a potential predictor of CTRCD and has clinical practical value.

## Low LVEF after chemotherapy was associated with blood RNA viruses

It has been hypothesized that immunosuppression after chemotherapy increases opportunistic viral infections (17). Varkoly et al. performed high-throughput sequencing analysis of RNA obtained from blood samples of 28 patients with hematological malignancies who had undergone chemotherapy. The result suggested that patients with low LVEF had influenza orthomyxovirus, avian paramyxovirus, and retrovirus sequences present. This is the first study to use high-throughput, blinded, unbiased sequencing to test for RNA viruses in circulating blood and associate those findings with abnormalities in heart function in patients who have recently finished chemotherapy. This study raises attention to RNA virus infections in individuals with chemotherapy-related cardiomyopathy.

## Cardiovascular outcomes in patients with colorectal cancer

Colorectal cancer (CRC) patients are potentially at high cardiovascular risk (18). Hang et al. followed up 197, 699 colorectal cancer patients for 37 months and examined the risks of cardiovascular death (CVD) in patients with CRC. They revealed that CVD ranked first and accounted for 41.69% of the major cause of non-cancer deaths. In addition, the nomogram for CVD prediction in CRC patients was created. This nomogram performed quite well and might assist physicians in providing customized care in clinical settings.

## Perspectives

With the generous support from all editors, publishers, reviewers, and authors involved in this research topic, we have successfully finalized this wonderful collection focusing on

mechanisms and therapeutic in Cardio-Oncology. Future studies on the mechanism and management of cardio-oncology are expected to continually improve the survival and life quality of cancer survivors. The enormous issues posed by tumor-cardiovascular comorbidity, however, deserve more attention given its rising incidence and the continuously aging population. There is substantial opportunity for the collaboration between oncologists and cardiologists to work together to improve the outcome of cancer patients with cardiovascular comorbidity.

## Author contributions

YM drafted the manuscript. DH and FC revised the paper. All authors listed have made a substantial, direct, and intellectual contribution to the work and approved it for publication.

**Background:** Doxorubicin (Dox) is one of the most effective chemotherapy agents used in the treatment of solid tumors and hematological malignancies. However, it causes dose-related cardiotoxicity that may lead to heart failure in patients. Luteolin (Lut) is a common flavonoid that exists in many types of plants. It has been studied for treating various diseases such as hypertension, inflammatory disorders, and cancer. In this study, we evaluated the cardioprotective and anticancer effects of Lut on Dox-induced cardiomyopathy *in vitro* and *in vivo* to explore related mechanisms in alleviating dynamin-related protein (Drp1)-mediated mitochondrial apoptosis.

**Methods:** MTT and LDH assay were used to determine the viability and toxicity of cardiomyocytes treated with Dox and Lut. Flow cytometry was used to examine ROS levels, and electron and confocal microscopy was employed to assess the mitochondrial morphology. The level of apoptosis was examined by Hoechst 33258 staining. The protein levels of myocardial fission protein and apoptosis-related protein were examined using Western blot. Transcriptome analysis of the protective effect of Lut against Dox-induced cardiac toxicity in myocardial cells was performed using RNA sequencing technology. The protective effects of Lut against cardiotoxicity mediated by Dox in zebrafish were quantified. The effect of Lut increase the antitumor activity of Dox in breast cancer both *in vitro* and *in vivo* were further employed.

**Results:** Lut ameliorated Dox-induced toxicity in H9c2 and AC16 cells. The level of oxidative stress was downregulated by Lut after Dox treatment of myocardial cells. Lut effectively reduced the increased mitochondrial fission post Dox stimulation in cardiomyocytes. Apoptosis, fission protein Drp1, and Ser616 phosphorylation were also increased post Dox and reduced by Lut. In the zebrafish model, Lut

significantly preserved the ventricular function of zebrafish after Dox treatment. Moreover, in the mouse model, Lut prevented Dox-induced cardiotoxicity and enhanced the cytotoxicity in triple-negative breast cancer by inhibiting proliferation and metastasis and inducing apoptosis.

**Keywords:** luteolin, cardiac dysfunction, doxorubicin, breast cancer, mitochondrial dysfunction

## INTRODUCTION

Doxorubicin (Dox), an anthracycline chemotherapeutic agent, has been widely used to treat a variety of tumors including breast cancer, ovarian cancer, and hematological malignancies (1–4). However, the clinical utility of Dox in chemotherapy is limited by its adverse dose-dependent cardiotoxicity, which often results in left ventricular dysfunction, cardiomyopathy, and even heart failure (5, 6). Over the decades, novel insights into Dox-induced oxidative stress in cardiomyocytes emerged since current interventions to lessen the incidence of cardiotoxicity after prolonged Dox treatments are unsatisfactory (7–9). Increasing evidence proved that Dox facilitates cardiomyocyte apoptosis and programmed death by damaging mitochondrial structure and its biologic function, which is ascribed to the disorder of mitochondrial oxidation-reduction homeostasis and mitochondrial dynamics (10). Nevertheless, effective interventions for Dox-induced cardiotoxicity still need to be explored and developed.

Dexrazoxane is the only drug currently approved by the FDA that provides protection against Dox-induced cardiotoxicity. However, dexrazoxane not only causes side effects, such as hematological toxicity and myelosuppression, but also decreases the antitumor efficacy of Dox (11, 12). For instance, the activation of hypoxia-inducible transcription factor, an oncogene, may contribute to the protective effect of dexrazoxane against anthracycline cardiotoxicity in dexrazoxane-treated H9c2 cardiomyocytes (13). Interestingly, numerous studies have demonstrated that different herbal products and bioactive phytochemicals could counterbalance Dox-induced cardiotoxicity as add-on therapies (14, 15). Therefore, developing a drug that confers cardioprotection during Dox treatment and improves the chemotherapeutic efficacy of Dox in cancer cells is important.

Luteolin (Lut), 3',4',5',7'-tetrahydroxyflavone, a naturally occurring flavone, which are widely enriched in plants. Lut has shown beneficial effects in several biological processes including anti-tumorigenesis, anti-inflammation, antiapoptotic activities, and antioxidative stress (Figure 1A) (16, 17). Plants rich in Lut have been used as traditional Chinese medicine (TCM) for hypertension, inflammatory diseases, and cancers (14, 18). In China, traditional herbal medicine has been commonly used for the treatment of breast cancer and its complications (19). Among them, *Platycodon grandiflorum* is widely used, alone or in combination with other herbal medicines, to treat patients with early breast cancer receiving anthracycline-based chemotherapy. Our previous clinical study found that *Platycodon grandiflorum* has cardioprotective effects for early breast cancer patients who received Dox-based chemotherapy (20). Basic experiment studies

revealed that *Platycodon grandiflorum* prevents Dox-induced cardiotoxicity in a mouse model of breast cancer (21). However, the potential mechanisms behind the cardioprotective effects remain unknown.

Lut is one of the major metabolites upon oral administration of luteolin-7-O-glucoside and is generally absorbed by intestinal mucosa into the systemic circulation after oral administration with an oral bioavailability at ~26% (22). Importantly, the flavonoid Lut is recognized as an important regulator of myocardial function providing myocardial protection during times of stress and can largely protect the myocardium against IR injury, partly through the downregulation of antioxidant and apoptosis properties (23, 24). Importantly, as the main component of *Platycodon grandiflorum*, Lut exerts multiple cellular effects *in vitro*, including antiproliferative effects in cancer cells and anti-inflammatory and antioxidative effects in various cell types. However, the molecular mechanisms by which Lut exerts these effects remain unclear.

Previous studies shown that Dox may activate apoptotic signaling through multiple mechanisms, including mitochondria-related apoptotic signaling (25). Dox-induced mitochondrial fission is a dynamin-related protein 1 (Drp1) signaling-dependent process, Drp1 might be a potential target against Dox-induced cardiotoxicity (26, 27). Given that hepatotoxicity and heart failure due to different medicines and toxins can be attenuated by Lut, we hypothesized that Lut may have protective effects on cardiotoxicity due to Dox via regulating mitochondrial damage. Therefore, the aim of this work was to investigate the protective effect of Lut against Dox-induced cardiotoxicity. The results showed that this protection was mediated through Drp1-regulated mitochondria-related apoptosis both *in vitro* and *in vivo*. In addition, Lut enhanced the chemotherapeutic efficacy of Dox in breast cancer.

## MATERIALS AND METHODS

### Cell Cultures

H9c2 (rat cardiomyocytes), AC16 (human cardiomyocytes), 4T1 (mouse breast cancer cell), and MDA-MB-231 (human breast cancer cell) cell lines were purchased from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). H9c2, AC16, and MDA-MB-231 cells were maintained in DMEM medium supplemented with 10% (v/v) FBS, 100 U/mL penicillin, and 100 mg/L streptomycin. The 4T1 cells were maintained in RPMI 1640 medium supplemented with 10% (v/v) FBS, 100 U/mL penicillin, and 100 mg/L streptomycin. The cells were incubated at 37°C in a 5% CO<sub>2</sub> incubator with saturated humidity.

## Cell Viability and Cytotoxicity Assays

The cell viability and cytotoxicity of H9c2 and AC16 cells were detected by MTT assay and LDH assays. Briefly, the cells were plated in 96-well plates at a density of 5,000 cells/well, incubated overnight, and then exposed to 1  $\mu$ M Dox with or without various concentrations of Lut for another 24 h. Cells were supplemented with 20  $\mu$ L MTT and incubated for 4 h at 37°C. The formazan crystals that formed were subsequently dissolved in 150  $\mu$ L DMSO, and the OD490 values were measured with a BioTek instrument (Winooski, Vermont, USA). For cytotoxicity assay, the release of LDH into the medium was determined using a Cytotoxicity Detection Kit (Beyotime, Shanghai, China). The absorbance was measured with a microplate reader at 490 nm.

## Oxidative Stress Analysis

After 24 h of Dox (1  $\mu$ M) treatment with or without Lut (20  $\mu$ M), H9c2 and AC16 cells were loaded with 10  $\mu$ M

DCFH-DA in medium for 30 min at 37°C. After incubation, the ROS levels were measured using a flow cytometer. For SOD analysis, cell supernatants were collected by centrifugation after treatment. The solution was measured by the WST-8 method according to the manufacturer's instructions. The SOD activity was presented as percent inhibition of the reduction of the chromogenic substrate.

## Cell Microfilament Cytoskeleton Staining

H9c2 and AC16 cells were seeded into 6-well plates. After 24 h of Dox (1  $\mu$ M) treatment with or without Lut (20  $\mu$ M), cells were fixed with 4% paraformaldehyde in PBS for 15 min. Suitable media were washed twice with wash buffer and permeabilized with 0.1% Triton X-100 in PBS for 5 min at room temperature. Following two washes with wash buffer, cells in suitable media were covered with dilute FITC-conjugated phalloidin in PBS immediately prior to use and incubated for 30 min to stain

the actin. Nuclei counterstaining was performed by incubating cells with 0.1  $\mu\text{g/mL}$  DAPI for 15 min. Fluorescence images were captured with a laser scanning confocal microscope.

## Cell Apoptosis Analysis

H9c2 and AC16 cells were seeded in 6-well flat-bottom microtiter plates at an initial cell density of  $10^5$  cells/well and cultured overnight. After 24 h of Dox (1  $\mu\text{M}$ ) treatment with or without Lut (20  $\mu\text{M}$ ), cells were incubated with fresh medium containing 0.1 mmol/L Hoechst 33258 (Beyotime, Shanghai, China) in the dark for 10 min. The cells were washed three times with PBS, and the apoptotic cells were observed under a fluorescence microscope (Olympus, Tokyo, Japan).

## Western Blot

Western blot was used to evaluate the apoptosis-related protein in cells. Primary rabbit antibodies, such as Bax (#2772, 1:1,000), Bcl-2 (#3498, 1:1,000), Bcl-XL (#2764, 1:1,000), Caspase-3 (#9662, 1:1,000), Cleaved Caspase-3 (#9664, 1:1,000),  $\beta$ -actin (#3700, 1:1,000), GAPDH (#5174, 1:1,000), Drp1 (#8570, 1:1,000), phospho-Drp1 (Ser616) (#3455, 1:1,000), and horseradish peroxidase (HRP)-conjugated secondary antibody (#7074s, 1:5,000) were purchased from Cell Signaling Technology, Inc. (Beverly, MA, USA). Cells were washed with PBS for three times and lysed with lysis buffer. After incubation on ice for 30 min, the lysates were centrifuged at 12,000 g for 15 min at 4°C. Protein sample was denatured at 100°C for 10 min, separated by sodium dodecyl sulfate–polyacrylamide gel electrophoresis, and then transferred to PVDF membrane (Millipore). The membrane was incubated with the primary antibodies overnight. Then, the membrane was washed and incubated with secondary HRP-conjugated goat anti-rabbit or anti-mouse antibodies. Finally, the blots were developed with Enhanced ECL System (Beyotime, Shanghai, China), and the signal was quantified by Quantity One software (Bio-Rad).

## Confocal Microscopy and Electron Assessment on Mitochondrial Morphology

Mitochondrial morphology was assessed by confocal microscopy. After 24 h of Dox (1  $\mu\text{M}$ ) treatment with or without Lut (20  $\mu\text{M}$ ), the media were removed from the dish, and staining solution containing MitoTracker probe (Yeasen Biotech, Shanghai, China) was added. The lyophilized MitoTracker was dissolved in anhydrous dimethyl sulfoxide to a final concentration of 100 nmol/L and incubated for 30 min. Images were captured with a laser scanning confocal microscope (Olympus, Tokyo, Japan). Following Dox treatment with or without Lut, the H9c2 and AC16 cells were washed with PBS, collected, and fixed in 2.5% glutaraldehyde for over 2 h at 4°C. The specimens were subsequently rinsed with PBS, fixed in 1% osmium tetroxide for 1–2 h, and then dehydrated sequentially in graded concentrations of 50, 70, 80, 90, and 100% ethanol for 15 min. The specimens were then processed for Epon<sup>TM</sup> embedding and observed under a transmission electron microscope (CM100, Philips, Netherlands).

## Molecular Docking

Molecular docking was used to interpret the binding area of small molecule ligands and macromolecular receptors through computer simulation and then calculate the physical and chemical parameters for predicting the affinity between the two. The mol2 format of the active ingredient was downloaded from the PubChem database. Its energy was minimized through Chem3D and converted into pdb format. Small molecule compounds were imported into AutoDock Tools-1.5.6 software. Water molecules were deleted, atomic charges were added, and atom type was allocated. All flexible keys can be rotated by default and finally saved as a pdbqt file. The PDB format file of the crystal structure of the target was downloaded from the PDB database (Protein Data Bank). Pymol 2.3 software was used to delete irrelevant small molecules in the protein molecule. Then, we imported the protein molecule into the AutoDock Tools-1.5.6 software to delete water molecules and add hydrogen atom, and finally saved it as a pdbqt file. The processed active ingredient is a small molecule ligand, and the protein target is used as a receptor. The center position and length, width, and height of the Grid Box were determined according to the interaction site of the small molecule and the target. Finally, batch docking was carried out through AutoDock vina and python script. In analyzing the molecular docking results, we visualized the binding effect of compounds and proteins using Pymol 2.3 software.

## RNA Sequencing

H9c2 and AC16 cells were harvested after drug treatment (three samples per group). The total RNA of each sample was extracted using TRIzol (Thermo Fisher). The quality of the RNA was measured by the Agilent 2100 Bioanalyzer with the RNA 6000 Nano Kit (Agilent, Santa Clara, CA, USA). The RNA concentration, RIN value and fragment length distribution were analyzed. Construction of the sequencing library and RNA sequencing were performed by Sangon (Shanghai, China) using the Illumina NovaSeq Platform.

## Identification of Differentially Expressed Genes (DEGs) and Functional Enrichment Analysis

Limma package (version 3.40.2) of R software was used to screen out the DEGs in the Dox–Lut group compared with Lut-treated group and Dox-treated group compared with control group in H9c2 and AC16 cells. “Adjusted  $P < 0.05$  and Log (Fold Change)  $> 1$ ” were defined as the cutoff for the identification of differentially expressed mRNAs. To further confirm the underlying function of potential targets, the data were analyzed by functional enrichment. Gene Ontology (GO) is a widely used tool for annotating genes with functions, especially molecular function (MF), biological pathways (BP), and cellular components (CC). Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis is a practical database for analytical study of functional annotations and associated high-level genome-wide pathways. The results of functional enrichment are displayed in bubble charts.

## Zebrafish Maintenance and Drug Treatment

Tg (cm1c2: GFP) zebrafish with GFP specifically expressed in myocardial cells were used in this study. Zebrafish were maintained as described in the Zebrafish Handbook (28). All animal experiments were approved by the Animal Research Ethics Committee of Shanghai University of Traditional Chinese Medicine. Pair-wise mating (6–12 months old) was used to generate the zebrafish embryos, which were maintained in embryo medium at 28.5°C. All embryos were then raised in the embryo medium containing 1-phenyl-2-thiourea (200 mM) after 48 hpf. Zebrafish (2 dpf) at the same developmental stage were distributed into a 24-well microplate (5 fish per well). After co-treatment with Dox (10 µM) and different concentrations of Lut (5, 10, 20 µM) for 24 h, ventricular functions of zebrafish were examined by assessing various parameters and morphology. The morphology and functions of zebrafish heart were measured by an imaging system comprising a microscope (Olympus). Zebrafish were placed into 1% low-melting-point agarose (Gibco) to restrict their movement, and videos of zebrafish heartbeat were recorded for 10 s at room temperature. The parameters and morphology of ventricular function of zebrafish were measured.

## Wound Healing Assay

Cells were seeded in 6-well plates at a density of  $1 \times 10^5$  cells per well, and when cellular confluence reached about 90%, a 200 µL pipette tip was used to create wounds in confluent cells. After removing the floating cells by washing the scraped surface with PBS, wounded monolayers were photographed with a microscope. Cells were then incubated containing Dox (2 µM) with or without Lut (40 µM) for 24 h. The images of cells migrating into the wound surface and the average distance of migrating cells were determined under a microscope 24 h later.

## Colony Formation Assay

To further determine the inhibitory effect of Lut on the tumorigenicity of triple-negative breast cancer (TNBC) cells, colony formation assays were performed. Five hundred 4T1 or MDA-MB-231 cells were seeded into 6-well plates to incubate overnight. The cells were then incubated with Dox (2 µM) with or without Lut (40 µM) for 7–10 days. After fixing with 4% paraformaldehyde and staining with a crystal violet solution, colonies containing more than 30 individual cells were counted under a stereomicroscope.

## Cell Invasion Assay

The invasive ability of 4T1 and MDA-MB-231 cells were measured using 24-well Transwell with polycarbonate filters (pore size, 8 µm) coated on the upper side with Matrigel (BD, Bedford, MA, USA).  $1 \times 10^3$  cells in 100 µL medium were seeded in the top chamber. The bottom chamber contained 10% fetal calf serum medium. After 24 h incubation, non-invasive cells were removed with a cotton swab. Cells that migrated to the bottom surface of the membrane were fixed in formaldehyde, stained with crystal violet solution, and counted under a microscope.

## Xenograft Mouse Experiments

Seven-week-old female BALB/c mice (18–20 g) were obtained from the Shanghai SLAC Laboratory Animal Technology Co., Ltd. (Shanghai, China). The animals were housed under standardized conditions in animal facilities at  $20 \pm 2^\circ\text{C}$  temperature,  $40\% \pm 5\%$  relative humidity, and a 12-h light/dark cycle with dawn/dusk effect. The protocol was approved by the Animal Research Ethics Committee of Shanghai University of Traditional Chinese Medicine (Permit Number: PZSHUTCM18122103). 4T1 cells ( $2 \times 10^6$ ) were resuspended in 10 mL PBS, and 100 µL of cell suspension was subcutaneously injected into the second pair of breast fat pads on the left side of each mouse. The tumors formed approximately 14 days after the inoculation. Then, all mice were randomly divided into three groups ( $n = 5$ ): control group (ip, saline), Dox group (ip, 2.5 mg/kg Dox), and Dox combined with Lut group (ip 2.5 mg/kg Dox + ip 30 mg/kg Lut). The mice were administered with Dox or Dox combined with Lut solution once per 2 days continuously for 2 weeks. At the experimental endpoint, all animals were euthanized. Then, the size and weight of tumors were measured. Lungs and tumors were excised and then fixed in 4% paraformaldehyde overnight until further analysis. For echocardiographic studies, the mice were anesthetized with 2.5% isoflurane in 95% oxygen and 5% carbon dioxide and then situated in the supine position on a warming platform to maintain the core temperature at  $37^\circ\text{C}$ . Cardiac function was evaluated via echocardiography by using a High-Resolution Small Animal Imaging System (Vevo2100, Visual Sonics Inc., Toronto, Canada). Two-dimensional and M-mode echocardiographic images of the long and short axis were recorded. Left ventricular ejection fraction (LVEF) and left ventricular fractional shortening (LVFS) were measured and calculated using the Vevo Strain Software Work Station.

## Statistical Analysis

All results are presented as mean  $\pm$  standard deviation (SD). Two-tailed analysis of variance followed by Dunnett's *post hoc* test and Fisher's test was used to determine the statistical significance.  $P < 0.05$  was considered significant for all tests.

## RESULTS

### Lut Attenuates Dox-Induced Cardiotoxicity in H9c2 and AC16 Cells

The H9c2 (rat) and AC16 (human) cardiomyocytes were treated with elevated concentration (0, 2.5, 5, 10, 20, and 40 µM) of Lut for 24 h. As shown in **Figure 1B**, cell viability was markedly increased with Lut ( $P < 0.05$ ). As detected by LDH assay, the increased Lut concentration was not significantly correlated with LDH release until the Lut concentration was increased to 40 µM ( $P < 0.05$ ; **Figure 1C**). Dox (0, 0.25, 0.5, 1, 2, 4, and 8 µM) treatment for 24 h markedly decreased cell viability ( $P < 0.01$ ; **Figure 1D**). Co-treatment with Lut and Dox significantly increased cell viability compared with Dox alone ( $P < 0.05$ ; **Figure 1E**). Lut could significantly attenuate Dox-induced cardiotoxicity in H9c2 and AC16 cells.

## Lut Attenuates Dox-Induced Oxidative Stress and Cytoskeletal Damages in H9c2 and AC16 Cells

We then detected changes of oxidative stress in H9c2 and AC16 cells after 24 h drug treatments using flow cytometry. The results showed that Lut treatment did not significantly change the ROS level, but it could significantly reduce the elevated ROS level induced by Dox ( $P < 0.05$ ; **Figures 2A,B**). Similarly, the decreased SOD activity induced by Dox could be significantly increased by Lut treatment, which could even reach a level higher than that in the Lut-alone group ( $P < 0.05$ ; **Figures 2C,D**). The integrity of the myocardial cytoskeleton plays an important role in the physiological function of the heart. Interestingly, cytoskeleton staining suggested that the cytoskeleton of the Dox treatment group was damaged with disappearance of microfilaments and microtubules in the cell membrane and loss of cell fiber tension. However, this damage could be markedly recovered by Lut in the combined treatment group (white arrows, **Figures 2E,F**). In conclusion, Lut could significantly attenuate Dox-induced oxidative stress and restore cytoskeletal alterations in H9c2 and AC16 cells.

## Lut Inhibits Dox-Induced Cardiomyocyte Apoptosis in H9c2 and AC16 Cells

TUNEL assay was performed to assess apoptosis following Lut and Dox treatment in H9c2 and AC16 cells (**Supplementary Figures 1A,B**). Compared with the control group, Dox challenge for 24 h significantly increased cell apoptosis as evidenced by the elevated number of TUNEL-positive cardiomyocytes ( $P < 0.05$ ), while the effect was significantly inhibited by Lut treatment ( $P < 0.05$ ; **Figures 3A,B**). Meanwhile, Western blot indicated that Dox treatment upregulated the levels of Bax and Cleaved Caspase-3 and downregulated Bcl-2 and Bcl-XL levels in H9c2 and AC16 cells. Importantly, the regulation induced by Dox was conversely regulated by Lut treatment ( $P < 0.05$ ; **Figures 3C,D**). Taken together, Lut treatment could significantly inhibit Dox-induced cardiomyocyte apoptosis through the Bax/Bcl-2/Caspase-3 pathway in H9c2 and AC16 cells.

## Lut Attenuates Dox-Induced Excessive Mitochondrial Division of H9c2 and AC16 Cells

Next, we explored the effect of Lut on the mitochondrial morphological change of cardiomyocytes induced by Dox. As shown in **Figure 4A**, fluorescence microscopy showed that the mitochondria of normal cardiomyocytes were reticulated. After being stimulated with Dox ( $1 \mu\text{M}$ ) for 24 h, compared with the normal group, cell mitochondria were divided, and the morphology of cell mitochondria changed significantly, transforming from a reticulate to a punctate phenotype. In addition, compared with the Dox-treated group, Lut ( $20 \mu\text{M}$ ) markedly inhibited the excessive division of mitochondria and restored the mitochondrial morphology of H9c2 and AC16 cells. Using transmission electron microscopy, we observed the ultrastructure of cells. After 24 h of Dox treatment, vacuoles

appeared in cardiomyocytes, and a “hair ball” structure appeared in the mitochondria (red arrow, **Figure 4B**). After Lut treatment, the morphology of cell mitochondria was restored, and the morphology of cell nucleus and chromatin returned to normal.

## Lut Attenuates Dox-Induced Drp-1 Phosphorylation in H9c2 and AC16 Cells

We tried to explore the mechanism of Lut to restore Dox-induced mitochondrial morphological alterations and used a molecular docking algorithm to predict the binding mode and affinity between the receptor and the drug molecule in **Figure 5A**. The results suggested a high affinity for docking between Drp-1 and Lut (affinity =  $-8.31 \text{ kcal/mol}$ ). Western blot revealed a significantly elevated p-Drp-1/Drp-1 ratio in the Dox-treated group, while the phosphorylation level of Drp-1 significantly decreased with additional Lut treatment in a dose-dependent manner compared with the Dox-treated group ( $P < 0.05$ ; **Figures 5B,C**). Overall, Lut could significantly attenuate Dox-induced mitochondrial morphological changes *via* regulating Drp-1 phosphorylation in H9c2 and AC16 cells.

## Lut Reduces Heart Damage Induced by Dox *in vivo*

The protective effects of Lut against cardiotoxicity mediated by Dox in zebrafish were quantified. As shown in **Figure 6A**, we constructed a zebrafish heart injury model using  $10 \mu\text{M}$  Dox. After co-administration of Dox and different concentrations of Lut for 24 h, the zebrafish pericardium of the model group showed obvious edema compared with the negative control group. Moreover, we found a significantly decreased zebrafish heart rate, increased SV-BA distance, and decreased stroke volume in the Dox-induced group ( $P < 0.05$ ; **Figures 6B–D**), indicating severe heart damage. Compared with the doxorubicin-induction group, we found significantly increased heart rate, shortened SV-BA distance, and markedly improved stroke volume of zebrafish after 24 h of intervention with medium and high doses of Lut ( $P < 0.05$ ; **Figures 6B–D**).

## Lut Interferes With Dox-Induced Transcriptome Sequencing of Cardiomyocytes in AC16 and H9c2 Cells

Subsequently, to identify DEGs and hallmarks related to the process of Lut in attenuating the toxicity of Dox to cardiomyocytes, we used RNA sequencing and selected upregulated DEGs in the Dox group compared with control group and downregulated DEGs in the Dox-Lut group compared with Dox group. We screened out a total of 137 overlapped hub genes in AC16 cells and 123 overlapped hub genes in H9c2 cells (**Figures 7A,B**). Similarly, we identified downregulated DEGs in the Dox group compared with the control group and upregulated DEGs in the Dox-Lut group compared with the Dox group. Then, we screened out a total of 32 overlapped hub genes in AC16 cells and 814 overlapped hub genes in H9c2 cells (**Figures 7A,B**). Next, we explored the functional annotations of different genes in cardiomyocytes using GO and KEGG algorithm. The DEGs were significantly involved in biological process (GO: BP),

**FIGURE 2 |** Effect of Lut treatment on Dox-induced oxidative stress and cytoskeletal damages in H9c2 and AC16 cells. **(A,B)** ROS and **(C,D)** SOD levels in H9c2 and AC16 cells after Dox and Lut treatment. **(E,F)** Cytoskeleton staining in H9c2 and AC16 cells after Dox and Lut treatment (630 $\times$ ). Mean  $\pm$  SD,  $n = 3$  independent experiment. \* $P < 0.05$  compared with control group. # $P < 0.05$  compared with Dox group.

**FIGURE 4 |** Effect of Lut treatment on Dox-induced changes in cardiomyocyte mitochondrial morphology. **(A)** Representative fluorescence images of the morphology of mitochondria in H9c2 (left) and AC16 (right) cells (630 $\times$ ). **(B)** Transmission electron microscopy images of the morphology of mitochondria in H9c2 (left) and AC16 (right) cells (12,000 $\times$ ). Red arrows show autophagosome.

cleavage furrow; and molecular function (GO: MF), including kinase regulator activity, GTPase activator activity, tubulin binding, cytoskeletal protein binding, and microtubule binding (Figures 7C–E). Additionally, DEGs of AC16 and H9c2 cells significantly participated in cellular senescence, AMPK signaling pathway, viral carcinogenesis, and human T-cell leukemia

virus 1 papillomavirus infection, suggesting that drug-induced cellular senescence may increase the virus susceptibility and carcinogenicity of cardiomyocytes (Figure 7F). We found that the DEGs not only markedly participated in Hippo/Wnt, AMPK/MAPK, and TGF- $\beta$  signaling pathways and animal mitophagy process, but were also involved in transcriptional

misregulation and pathways in cancers, such as hepatocellular, breast, gastric, and thyroid cancer.

### Lut Promotes the Antitumor Effect of Dox in 4T1 and MDA-MB-231 Cells

To further explore the effect of Lut on the antitumor efficacy of Dox, we explored the malignant biological behavior of different treatments in invasive TNBC 4T1 and MDA-MB-231 cell lines. As shown in **Figures 8A,B**, the cell viability was markedly decreased in the Lut-added group compared with the Dox-induced group in 4T1 and MDA-MB-231 cells ( $P < 0.05$ ). Wound healing test showed significantly reduced wound width after 24 h of induction of Lut or Dox compared with the negative control group, while the combination of Lut and Dox remarkably decreased wound healing width compared with

the single-drug treatment group ( $P < 0.05$ ; **Figures 8C,D**). In addition, Lut significantly enhanced the antitumor efficacy of Dox by decreasing the colony formation and invasion ability of breast cancer cells ( $P < 0.05$ ; **Figures 8E-H**). In general, Lut could not only significantly inhibit the malignant behavior of tumor cells, but also enhance the antitumor efficacy of Dox in 4T1 and MDA-MB-231 cells.

### Lut Promotes Dox-Induced Cell Apoptosis via the Bax/Bcl-2/Caspase-3 Pathway in 4T1 and MDA-MB-231 Cells

Next, we explored the effect of Lut on the apoptosis of triple-negative breast cancer cells induced by Dox. Western blot indicated upregulated levels of Bax and Cleaved Caspase-3 in conjunction with downregulated Bcl-2 levels in Dox-treated

or Lut-treated 4T1 and MDA-MB-231 cells. Importantly, the regulation of cell apoptosis induced by Dox was significantly enhanced by additional Lut treatment ( $P < 0.05$ ; **Figures 9A,B**).

Taken together, Lut treatment could significantly enhance Dox-induced tumor cell apoptosis through the Bax/Bcl-2/Caspase-3 pathway in 4T1 and MDA-MB-231 cells.

## Lut Prevents the Cardiotoxicity and Promotes the Antitumor Effect Induced by Dox *in vivo*

A xenograft of 4T1 cells in 7-week-old BALB/c mice was established for *in vivo* exploration (**Figure 10A**). Echocardiographic examination showed that the Dox-treated group had an  $\sim 20\%$  decrease in LVEF and LVFS compared with the control group. Lut treatment significantly attenuated cardiac dysfunction in the Dox-treated mice, as indicated by the increased LVEF and LVFS ( $P < 0.05$ ; **Figure 10B**). Additionally, Dox did not alter the cardiac structure, including the diastolic left ventricular internal dimension (LVIDd), diastolic left ventricular posterior wall (LVPWd), and diastolic interventricular septum (IVSd) (**Supplementary Figure 2**). As shown in **Figure 10C**, the tumor volume and weight were significantly decreased in the Dox-induced group compared with the control group and was even further reduced in the Dox–Lut group ( $P < 0.05$ ; **Figure 10C**). Notably, Lut also significantly enhanced the Dox-induced reduction of the number of lung metastatic nodules in xenograft models ( $P < 0.05$ ; **Figure 10D**). Taken together, Lut could significantly promote the antitumor efficiency induced by Dox in a xenograft of highly aggressive 4T1 cells.

## DISCUSSION

Breast cancer is one of the most prevalent malignancies and associated with significant morbidity among females worldwide (29). Among the treatments of primary breast cancer, an anthracycline-based regimen is the standard of care (29, 30). According to the latest National Comprehensive Cancer Network guidelines, 5-fluorouracil, epirubicin, and cyclophosphamide adjuvant chemotherapy regimen followed by paclitaxel or paclitaxel combined with anti-human epidermal growth factor-2 trastuzumab is the recommended regimen for breast cancer (31). Anthracyclines represented by Dox are the first-line chemotherapy for breast cancer, and they play an irreplaceable role in current clinical treatment of breast cancer. Unfortunately, the adverse effects of Dox, such as immunosuppression, hepatotoxicity, and especially dose-dependent cardiotoxicity, limit its efficacy and application because treatment-related cardiotoxic adverse events have become one of the common causes of breast cancer mortality (32, 33). Current prevention and treatment cannot effectively solve the problem of Dox-induced cardiotoxicity (34, 35). Therefore, improved approaches to reduce Dox side effects and enhance Dox efficiency need to be developed.

TCM becoming increasingly important in cancer treatment and modern cardiotoxicity protective pharmacology. The identification of cardiotoxic protective drugs with unique pharmacological effects from TCM has become a new direction (36). For example, Zheng et al. found that the TCM Bu-Shen-Jian-Pi-Fang could inhibit tumor proliferation by enhancing GLUT-1 related glycolysis and may alter the immune-rejection microenvironment in renal cell carcinoma patients (37). Ginsenoside Re functions as an antioxidant, protecting cardiomyocytes from oxidant injury induced by exogenous and endogenous oxidants, and protects against apoptotic cell death (38, 39). Notably, previous attempts to explore the cancer prevention and therapeutic potential of Lut have systematically indicated its potential as an anticancer agent for various cancers (40). Lut can attenuate antitumor activity and drug resistance via reducing Bcl-2 expression in cancer cells (41). Interestingly, a previous study demonstrated the protective features of Lut against Dox-induced cardiotoxicity, possibly related to its ability of improving Drp1-regulated mitochondrial morphology alteration (42). However, it emphasized on TFEB-mediated mitochondrial regulation and the association between Drp-1 and mTOR, thus ignoring the positive effect of Lut in inhibiting Dox-induced cardiotoxicity in cardiomyocytes and tumor cells.

This study showed that Lut, the core component of *Platycodon grandiflorum*, markedly reduced the level of apoptosis and inhibited the activation of the Bax/Bcl-2/Caspase-3 signaling pathway of cardiomyocytes induced by Dox. Moreover, cytoskeleton damage ruptures cardiomyocytes in Dox-induced cardiotoxicity (43). In this work, Lut protected the cardiomyocyte cytoskeleton damage caused by Dox and maintained the integrity of the cardiomyocyte cytoskeleton. Therefore, cardioprotection from the perspective of protecting the cytoskeleton may be an effective target of Lut for the treatment of Dox-induced cardiotoxicity.

Cardiac autophagic processes lead to ROS overproduction and  $\Delta\psi_m$  dissociation, contributing to mitochondria-mediated apoptosis and death (44, 45). Our present work confirmed that Lut effectively reduced the level of cardiomyocyte oxidative stress and mitochondrial autophagy and inhibited mitochondrial division and the recruitment of Drp-1 phosphorylation. Subsequently, we performed transcriptome analysis to further explore the protective role of Lut in Dox-induced cardiotoxicity. Consistent with previous research (46), our findings indicated the role of Lut in the regulation of mitochondrial morphology, such as Ras protein signal transduction, microtubule cytoskeleton organization, cytoskeletal protein binding, and microtubule binding of molecular function, in GO enrichment analysis. Moreover, we found that the DEGs not only markedly participated in the Hippo/Wnt, AMPK/MAPK, and TGF- $\beta$  signaling pathways and animal mitophagy process, but were also involved in apoptosis, transcriptional misregulation, and pathways in cancers, such as hepatocellular, breast, gastric, and thyroid cancer. In light of the findings, we carried out follow-up studies on breast cancer cells (4T1

and MDA-MB-231). Notably, Lut exerted a protective effect on Dox-induced cardiotoxicity, improved cardiac function parameters, and enhanced the anticancer therapeutic effects of Dox *in vivo*. Interestingly, combined treatment of Lut and Dox alleviated cardiomyocyte apoptosis but enhanced the apoptosis of breast cancer cells, which were in accordance with previous pharmacokinetics studies highlighting that *Platycodon grandiflorum* combined with Dox can increase the concentration of Dox in the lung and tumor and decrease the concentration of Dox in the heart of breast cancer mice (21). Doubtlessly, the comprehensive findings of Lut and Dox combination in cardiomyocytes and breast cancer cells facilitate its clinical application.

The innovation of this research lies in the mutual verification of *in vivo* and *in vitro* experiments. For the first time, we studied the protective effect of Lut on Dox cardiotoxicity on the basis of a transgenic zebrafish animal model. Second, this study first explored the effect of Lut, the active ingredient of *Platycodon grandiflorum*, on the mitochondrial fusion-division process of cardiomyocytes and the role in the Drp1-Caspase apoptosis signaling pathway. Third, on the basis of transcriptomic sequencing, the mechanism of Lut inhibition of Dox cardiotoxicity was validated in cardiomyocytes and breast cancer cells, which shed light on increasing clinical significance to novel treatment strategies.

Despite the strengths of this study, a number of experimental limitations existed in this study. First and foremost, our study was a cell lines-based study lacking the Dox-induced neonatal rat left ventricle myocyte cardiotoxicity model. Lut retards Dox cardiotoxicity in-depth work is needed in neonatal rat left ventricle myocyte. In addition, the regulation of Lut on Drp-1 phosphorylation and potential binding site remains to be elucidated. Meanwhile, the molecular mechanism of Drp1-dependent mitochondrial autophagy remains unclear. Moreover, the opposite mechanism of Lut-induced apoptosis has not been fully elucidated in cardiomyocytes and tumor cells, more in-depth work is needed for the precise mechanism.

## CONCLUSION

The protective effect of Lut against Dox-induced cardiac dysfunction is associated with alleviating Drp1-mediated mitochondrial dysfunction. This study first revealed that Lut could potentiate the anticancer effects of Dox in breast tumor cells via the Bax/Bcl-2/Caspase-3 pathway.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories

and accession number(s) can be found below: NCBI; PRJNA763722, PRJNA763517.

## ETHICS STATEMENT

The animal study was reviewed and approved by Shanghai University of Traditional Chinese Medicine.

## AUTHOR CONTRIBUTIONS

YS, FL, MS, and CS conducted the experiments. YS analyzed the data and wrote the manuscript. WH, CW, YX, SZ, HG, JY, and ZZ designed the study and revised the manuscript. DG, YQ, and XH supplied technical support. SL provided all of the reagent. All the authors edited and commented on the manuscript.

Cyclophosphamide (CYP)-induced cardiotoxicity is a common side effect of cancer treatment. Although it has received significant attention, the related mechanisms of CYP-induced cardiotoxicity remain largely unknown. In this study, we used cell and animal models to investigate the effect of CYP on cardiomyocytes. Our data demonstrated that CYP-induced a prolonged cardiac QT interval and electromechanical coupling time courses accompanied by JPH2 downregulation. Moreover, N6-methyladenosine (m6A) methylation sequencing and RNA sequencing suggested that CYP induced cardiotoxicity by dysregulating calcium signaling. Importantly, our results demonstrated that CYP induced an increase in the m6A level of JPH2 mRNA by upregulating methyltransferases METTL3, leading to the reduction of JPH2 expression levels, as well as increased field potential duration and action potential duration in cardiomyocytes. Our results revealed a novel mechanism for m6A methylation-dependent regulation of JPH2, which provides new strategies for the treatment and prevention of CYP-induced cardiotoxicity.

**Keywords:** cyclophosphamide, cardiotoxicity, JPH2, m6A methylation, METTL3, cardiomyocyte

## INTRODUCTION

Although improved treatments have been effective in increasing the survival of patients with tumors, an increase in the number of side effects of cancer treatment have led to mortality (1, 2). Tumor therapy-induced cardiotoxicity as a common side effect has received increasing attention. Many countries and regions have issued relevant practice guidelines for cardiovascular toxicity induced by cancer treatments (3). Both conventional chemotherapies and targeted drug therapies reportedly induce cardiovascular toxicity events. One traditional antineoplastic agent, cyclophosphamide (CYP), is employed in the treatment of various cancers, including breast, lymphoid, and hematologic malignancies (4). Up to 28% of patients who received a high dose of CYP suffered from cardiac arrhythmias (3) and even heart failure (5). Further, CYP is widely used

in the treatment of other diseases, such as refractory neuromyelitis optica spectrum disorder (200 mg/kg) (6) and rapidly progressive systemic sclerosis (300 mg/kg) (7), all of reportedly cause severe cardiotoxicity. Even in the clinic, oral administration of a low dose (50 or 100 mg/day) for systemic sclerosis or lupus erythematosus for 1 week has caused cardiac electrical alteration (prolonged QT interval) in some patients. However, little is known about the mechanism underlying CYP-related cardiovascular toxicity. In particular, CYP has often been used in combination with other antineoplastic agents, including anthracyclines, docetaxel, and trastuzumab. This has led to difficulty in assessing the contribution of CYP in multidrug schemes (8).

CYP and other alkylating agents are the most common types of DNA damaging agents used in the treatment of various cancers. Alkylating agents exhibit pharmacological toxicity by adding methyl and other hydrocarbon groups to the DNA bases, resulting in base mutations, pair mismatches, and eventually fatal DNA cytotoxicity (9). The pharmacological mechanism is fatal to rapidly proliferating tumor cells. However, the cardiac cytotoxicity induced by alkylating agents is rarely discussed for non-proliferating cardiomyocytes. Because alkylating agents adduct DNA bases (A, T, G, and C) to induce DNA methylation (9), alkylating agents might affect RNA methylation. N<sup>6</sup>-adenosine methylation (m6A) of RNA transcripts is the most prevalent RNA modification (10). This modification regulates RNA stability (11), gene expression (12), mRNA alternative splicing (13), embryonic and stem cell differentiation (13–15), and various diseases including cancer (16) and cardiac dysfunctions (11, 17). Hence, we hypothesized that CYP induces cardiotoxicity through RNA m6A modification.

We treated rat neonatal cardiomyocytes (NRCMs), human embryonic stem cell-derived cardiomyocytes (hESCs-CMs), and a rat model with CYP to explore solutions for this problem. This was followed by combining action and field potential detections, RNA sequencing, and RNA m6A methylation analysis to explore the toxicity mechanism underlying CYP-induced cardiac electrical and mechanical alterations. Our results may provide drug targets and preventive measures for treating CYP-induced cardiotoxicity.

## MATERIALS AND METHODS

### Animals

All Sprague-Dawley (SD) rats in this study were purchased from Beijing Vital River Laboratory Animal Technology Company (Beijing, China). Twelve 8-week-old male SD rats with a mean weight of  $273.7 \pm 3.2$  g were randomized into two groups: six rats were subjected to saline (Double Crane Pharmaceutical Co. Ltd, Wuhan, China) peritoneal injection (vehicle group), whereas six rats were intraperitoneally injected with CYP (Jiangsu Hengrui Medicine Co., Ltd, Lianyungang, China) at a dose of 100 mg/kg (CYP treatment group). Echocardiography (echo) and electrocardiography (ECG) were performed at different time points (0, 1, and 3 days).

### In vivo ECG Recording

Continuous recordings of heart rate were obtained with a surface ECG. Rats were anesthetized with 3% isoflurane and were subsequently fixed on a wooden board. ECG recording was performed using the limb lead. Three electrodes on an ECG monitor were inserted into the subcutaneous tissues of the rats' left and right shoulders and the right hind leg. The signal was amplified and recorded on a personal computer using an ECG Processor (EP-2B, Softron Beijing Incorporated, China) and stored on a data acquisition program (SP2006, Softron Beijing Incorporated, China).

### ECG and Electromechanical Coupling Time Measurement

ECG measurement was performed as described previously (18). ECG was performed using a Vevo 2,100 system (FUJIFILM VisualSonics, Canada), and the cardiac dimensions and functional parameters were measured. The tissue Doppler imaging (TDI) echo combined with ECG was used to measure the electromechanical coupling time at the lateral wall of the left ventricle as described previously (19).

### Neonatal Rat Cardiac Myocytes Culture

NRCMs were isolated from newborn SD rats aged 1–2 days as described previously (20). These isolated NRCMs were grown in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum and 100 U/ml penicillin/streptomycin, and maintained at 37°C in 5% CO<sub>2</sub>.

### Cardiac Differentiation of Human Embryonic Stem Cells (hESC)

H9 human embryonic stem cells were purchased from the Beijing Cellapy Biological Technology Company (Cellapy, China). H9 cells were cultured and differentiated into cardiomyocytes following previously described procedures (21). In brief, H9 cells were cultured on 35-mm dishes (Corning, USA) with PSCeasy hESC culture medium (Cellapy, Beijing, China). Cells were cultured to reach ~90% confluency and differentiated into ESC-CMs using a chemical method as described previously (22). Immunofluorescent staining with primary antibodies against TNNT2 (Santa Cruz, USA) and  $\alpha$ -actinin (Abcam, UK) validated the purity of human cardiomyocytes.

### Immunofluorescence

Cells were cultured on glass slides, washed with PBS three times, fixed in 4% paraformaldehyde for 5 min, and then permeabilized with PBS containing 0.5% Triton X-100 (Sigma, USA) for 10 min. After 1 h of blocking with 5% BSA (Amresco, USA), the slides were incubated with primary antibodies followed by incubation with secondary antibodies. After the slides were washed, they were studied with a confocal fluorescence imaging microscope (DMI 4000B, Leica, Germany). The primary and secondary antibodies and their appropriate dilutions are listed in **Supplementary Table 1**.

## Microelectrode Array (MEA) Analysis

MEA recording in cardiomyocytes was performed as described previously (23). In brief,  $2 \times 10^4$  cells were plated on CytoView MEA plates (Axion Biosystems, USA) pre-coated with 5% matrigel, followed by treatment with CYP at different concentrations (0 and 500  $\mu\text{mol/L}$ ). The experimental data were acquired using a Maestro EDGE (Axion Biosystems, USA) according to the MEA operation manual.

## RNA Extraction and Quantitative Real-Time PCR

Total RNA was extracted from NRCMs using the TRIzol reagent (Invitrogen) and subjected to reverse transcription (RT) and real-time PCR. The primers used are listed in **Supplementary Table 2**. RT was performed using a 2,720 Thermal Cycler (Applied Biosystems, USA). Real-time PCR was performed using a QuantStudio 3 apparatus (Applied Biosystems, USA).

## Western Blot Analysis

Proteins were extracted from cells in RIPA lysis buffer (Solarbio, China) containing 1 mmol/L PMSF (Solarbio, China) and protease inhibitor cocktail (Bimake, China) for western blot analysis. In total, 50  $\mu\text{g}$  of protein were subjected to SDS-PAGE, transferred to a PVDF membrane (Millipore, USA), and incubated with the primary antibodies. These primary antibodies and their appropriate dilutions are listed in **Supplementary Table 1**. The membrane was then incubated with HRP-conjugated goat anti-mouse IgG (1: 2000, ZSGB-BIO) or HRP-conjugated goat anti-rabbit IgG (1: 2000, ZSGB-BIO). GAPDH was used as a control. Protein levels were determined using the Immobilon<sup>®</sup> Western Chemiluminescent HRP substrate (Millipore, UK).

## Cell Treatments

In the CYP treatment assays, 250, 500, and 750  $\mu\text{mol/L}$  of CYP (Selleck, USA) were added to the cell complete culture medium for 2 or 4 days for NRCMs and for 2 or 5 days for hESCs-CMs. To impede the expression of METTL3 in cardiomyocytes, adenoviruses harboring the specific small interference RNA (siRNA) sequences of METTL3 were used individually to infect cardiomyocytes at an optimized MOI for 24 h, followed by treatment with 500  $\mu\text{mol/L}$  CYP for an additional 24 h as the MEA assay. The siRNA and negative control (NC) sequences used are listed in **Supplementary Table 2**.

## RNA m6A Dot Blot Assay

An RNA m6A dot blot assay was performed as previously described (24). In brief, 1.5  $\mu\text{g}$  of total RNA was spotted onto a positively charged nylon-based membrane (GE Healthcare), blocked with 5% milk at room temperature for 2 h, and incubated with anti-m6A antibodies (1: 2000, Abcam) at 4 °C overnight and secondary antibodies (1: 3000, Abcam) at room temperature for 2 h. The same RNAs were spotted on the positively charged nylon-based membrane and stained with 0.02% methylene blue in 0.3M sodium acetate (pH 5.2), which ensured loading consistency among different samples.

## Methylated RNA Immune Precipitation (MeRIP) Sequencing

High throughput m6A sequencing was performed with the support of Kangchen Biotech (Shanghai, China). Briefly, total RNA was extracted from NRCMs treated with 500  $\mu\text{mol/L}$  CYP or DMSO (solvent control) for 48 h, followed by random fragmentation to 100–150 nucleotides using RNA fragmentation reagents. Fragmented RNA was subjected to m6A antibody immunoprecipitation following the Magna MeRIP m6A kit protocol (17-10499, Merk Millipore, USA) as described previously (25). An RNA library from immunoprecipitated RNA and input RNA was created on an Illumina HiSeq platform. Differential m6A peaks (fold change  $\geq 1.5$  and  $P \leq 0.05$ ) between CYP and solvent controls were used for gene ontology (GO) enrichment and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis.

## Ca<sup>2+</sup> Imaging

Ca<sup>2+</sup> imaging in cardiomyocytes was performed as described previously (21). In brief, hESCs-CMs inoculate with the green fluorescent calcium-modulated protein (GCaMP) calcium sensor (H9-GCaMP-CMs) were seeded onto confocal dishes. Confocal microscope (Leica, TCS5 SP5, Germany) was used for intracellular calcium imaging. Spontaneous Ca<sup>2+</sup> transients were recorded at 37°C and 5% CO<sub>2</sub> according to the standard line-scan methods (26, 27). A total of 8,192 line scans were acquired for a duration of 8.192 s. The imaging results were analyzed using the Image J and Igor pro software.

## Statistical Analysis

All statistical analyses were conducted using the SPSS 20.0 software (IBM Corp., USA) and Graphpad Prism software (version 8.0, GraphPad Software Inc., USA). The data are expressed as the mean  $\pm$  standard error (SE). A Student's *t*-test detected the differences between groups. *P* values of  $\leq 0.05$  were considered as statistically significant.

## RESULTS

### CYP Increased the Field Potential Duration and Decreased the Contractile Amplitudes of Cardiomyocytes

To clarify the cellular significance of CYP in cardiomyocytes, we first performed the CCK-8 assay to examine the effects of CYP on the viability of cardiomyocytes. The result confirmed that CYP had no significant effect on NRCMs viability (**Supplementary Figure 1A**). However, we observed that the levels of atrial natriuretic factor (ANP) and brain natriuretic peptide (BNP) had increased after NRCMs were treated with 500  $\mu\text{mol/L}$  CYP for 48 h (**Supplementary Figures 1B,C**). These results suggested that CYP induced slight cardiotoxicity, but did not affect cell viability. CYP was closely associated with cardiac arrhythmias related to QT prolongation and the acute and chronic toxicity of chemotherapy (3). A prolonged QT interval is an important monitoring indicator for myocyte toxicity caused by anticancer agents according to the guidelines issued by

the International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (28). Therefore, we seeded cardiomyocytes on multielectrode array (MEA) probes to evaluate the effect of CYP on myocardial electrophysiological properties. The time between depolarization and repolarization is the FPD (**Figure 1A**), which corresponds to the QT interval in an ECG. Compared with solvent control (CON), the FPD of NRCMs treated with CYP increased at 12, 24, and 48 h (**Figure 1B**). Meanwhile, the impedance of the CON cells showed no significant changes (**Figure 1C**). We observed that the impedance of NRCMs treated with CYP decreased with time (**Figure 1D**). These observations indicated that CYP negatively regulated the rhythm and contractility of cardiomyocytes.

Furthermore, we used human embryonic stem cell-derived cardiomyocytes (hESCs-CMs) (**Supplementary Figure 1D**) to evaluate the effect of CYP on cellular viability. Consistent with this finding in NRCMs, CYP had no significant effect on the viability of hESCs-CMs (**Supplementary Figure 1E**) but increased the RNA levels of ANP and BNP (**Supplementary Figures 1F,G**). Intriguingly, exposing hESCs-CMs to CYP (500  $\mu\text{mol/L}$ ) for 9 days resulted in a significant increase in FPD (**Figure 1E**) and reduction of contractile amplitudes (**Figure 1F**). These results supported QT interval prolongation and cardiac contractile dysfunction in rats.

## CYP-Induced Cardiac Electrical and Mechanical Alterations and Decreased Cardiac Contractile Function in Rats

To further investigate the effect of CYP on cardiac functions, we used intraperitoneally injected CYP to treat the rats with CYP at a dose of 100 mg/kg, which was converted from the clinical dose for treatment of cancer. *In vivo* ECG recording data (**Figure 2A**) showed QT interval prolongation in rats after CYP-treatment for 1 day compared with that in rats administered saline ( $82.17 \pm 1.70$  vs.  $65.17 \pm 3.02$  ms,  $P < 0.001$ ; **Figure 2B**). Corrected QT interval (QTc) prolongation also showed the same variation as QT prolongation ( $199.83 \pm 4.03$  vs.  $167.67 \pm 6.83$  ms,  $P < 0.01$ ; **Figure 2C**). Further, the prolonged QT and QTc would restore to preadministration levels after CYP-treatment for 3 days (**Supplementary Figures 2A,B**). These results were consistent with the clinical side effects of CYP.

Electromechanical coupling disturbances were closely related to the long QT syndrome (29, 30). Hence, we further explored the effect of CYP on cardiac electrical and mechanical alterations. Four electromechanical coupling time courses (Qsb, Qst, Rsb, and Rst) were measured with TDI echo combined with ECG (**Figure 2D**). The measurement results showed that four electromechanical coupling time courses in CYP-treated rats were longer than those in saline controls (**Figures 2E–H**), particularly in terms of Qst and Rst courses ( $P < 0.05$ , **Figures 2E,G**). Moreover, ultrasound echocardiography (**Figure 2I**) showed that the fractional shortening percentage (FS%; **Figure 2J**) and left ventricular ejection fraction (LVEF; **Figure 2K**) were significantly

lower in rats after CYP-treatment for 1 day. These results suggested that CYP induces cardiac electrical and mechanical alterations and decreases the excitation-contraction (E-C) coupling efficiency, leading to cardiac contractile dysfunction. Consistent with the results of QT and QTc, the prolonged electromechanical coupling time courses would restore after CYP treatment for 3 days (**Supplementary Figures 2C–F**) and the decreased FS and LVEF induced by CYP also showed a regression in CYP-treated rats after 3 days (**Supplementary Figures 2G,H**).

## CYP-Induced the Decrease of JPH2 Expression in Cardiomyocytes

Previous studies demonstrated that junctophilin-2 (JPH2) that anchor the sarcoplasmic reticulum to T-tubules is the key regulator of  $\text{Ca}^{2+}$  influx between L-type  $\text{Ca}^{2+}$  channels (LCCs) and ryanodine receptors (RyRs) and E-C coupling in cardiomyocytes (31, 32), is reportedly associated with atrial fibrillation (33) and arrhythmias (34). Based on the phenomena observed in the above cell and animal experiments, we further investigated the effect of CYP on JPH2 expression in NRCMs and hESCs-CMs at different treatment time points. Notably, a dose-dependent reduction in JPH2 RNA and protein levels occurred in NRCMs treated with CYP for 2 or 4 days (**Figures 3A,B**). Similarly, different concentrations of CYP treatments decreased JPH2 both in RNA and protein levels at day 2 or 5 in hESCs-CMs (**Figures 3C,D**). Similarly, JPH2 downregulation occurred in heart tissues of rats treated with CYP (**Supplementary Figure 3**). These results suggested that CYP induced cardiac electrical and mechanical alterations and cardiac contractile dysfunction by decreasing the expression of JPH2.

To explore the underlying mechanisms involved in the suppression effects of CYP on JPH2 expression in cardiomyocytes, we further investigated the effect of CYP on miR-24 and miR-331 expressions, which were shown to inhibit the expression of JPH2 in our previous studies (31, 35). The real-time PCR analysis revealed that the expression of miR-24 and miR-331 did not significantly change in NRCMs after CYP treatment for 2 days (**Supplementary Figures 4A,B**). Therefore, it suggested that CYP decreased JPH2 expression through other transcriptional regulatory mechanisms.

## CYP-Induced Substantial m6A Changes in Cardiomyocytes

N6-methyladenosine (m6A) is the most prevalent modification that widely exists in mRNAs, which is associated with post-transcriptional gene expression regulation (12), and mRNA stability (36). We next investigated whether CYP plays an important role in m6A RNA methylation in NRCMs, considering that CYP can induce nucleic acid methylation. The m6A dot blot testing showed that total m6A levels significantly increased in NRCMs treated with CYP for 2 days (**Figures 4A,B**). Next, methylated RNA immune precipitation sequencing (MeRIP-seq) was performed to compare the global profiling of m6A

**FIGURE 1 |** CYP increased the field potential duration (FPD) and decreased contractile amplitudes of cardiomyocytes. **(A)** Schematic of FPD of cardiomyocytes. **(B)** The FPD analysis of NRCMs with 500  $\mu\text{mol/L}$  of CYP at 0, 6, 12, 24, and 48 h. **(C)** Representative images of the relative cell amplitude of NRCMs treated with solvent control (CON) or CYP. The data were shown as the mean of triplicate experimental wells. **(D)** The cell amplitude analysis of NRCMs treated with 500  $\mu\text{mol/L}$  CYP at 0, 6, 12, 24, and 48 h. The FPD **(E)** and cell amplitude **(F)** analysis of hESCs-CMs treated with 500  $\mu\text{mol/L}$  CYP at 1, 2, 3, 4, 7, 8, and 9 days. The data are shown as the mean  $\pm$  SE,  $n = 3$ . \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$  vs. CON.

target genes between solvent controls and CYP-treated NRCMs. As shown in **Figure 4C**, the sequence motif “GGAC” was highly enriched in m6A immunoprecipitated RNAs, consistent with the findings of previous studies (37, 38). We found 585 significantly increased m6A peaks distributed in 259 genes, whereas 277 genes had 548 statistically decreased m6A peaks in CYP-treated NRCMs relative to controls. Notably, we observed that reduced m6A peaks were mainly localized in the 5' untranslated region (5' UTR), whereas increased m6A peaks were distributed in the coding sequence (CDS) and 3' untranslated region (3' UTR; **Figure 4D**). The pie charts showed that these statistically differentially distributed m6A peaks were mainly noted in the CDS and 3' UTR of genes in CYP-treated NRCMs regarding CON cells (**Figure 4E**). To explore the physiological and pathological significance of m6A modification after CYP treatment, we analyzed the KEGG pathway on

the significantly altered m6A peaks. Our results showed that upregulated m6A peaks in the CYP-treated NRCMs were significantly related to the cAMP signaling pathway, adrenergic signaling in cardiomyocytes, calcium signaling pathway, GnRH signaling pathway and other dysregulation pathways in cancer (**Figure 4F**).

Furthermore, RNA sequencing was also performed on NRCMs treated with solvent control (CON) or CYP. Compared with CON, 369 genes were significantly downregulated, and 74 genes were upregulated in the CYP-treated group (**Supplementary Figure 5A**). The GO enrichment and KEGG analysis of the total DEGs showed that these DEGs were enriched in the NF- $\kappa$ B, TNF, and calcium signaling pathways (**Supplementary Figures 5B,C**). Remarkably, with the combined MeRIP-seq and RNA-seq results, we found upregulated m6A methylation sites in

**FIGURE 2 |** The effect of CYP on QT intervals, cardiac electromechanical coupling and cardiac function. the 5'UTR and CDS of JPH2 mRNA, accompanied with the downregulation of JPH2 expression on the RNA level. These results suggested that CYP induces calcium signaling changes through JPH2 downregulation caused by increasing m6A modification.

### CYP-Induced Calcium Handling Abnormalities in hESCs-CMs

Calcium is a fundamental regulator of E-C coupling and electrophysiological signaling in cardiac myocytes (39). The above MeRIP-seq and RNA-seq results showed that

the calcium signaling pathway played an important role in CYP-induced cardiotoxicity. We next verified and analyzed the  $\text{Ca}^{2+}$  handling properties of hESCs-CMs with CYP treatment by using H9-GCaMP derived cardiomyocytes (H9-GCaMP-CMs) (21). Compared with CON, hESCs-CMs treated with different concentrations of CYP (250, 500, and 750  $\mu\text{mol/L}$ ) demonstrated significant  $\text{Ca}^{2+}$  transient irregularities, which were virtually absent in CON cells. As shown in Figure 5A, H9-GCaMP-CMs treated with 250  $\mu\text{mol/L}$  CYP showed no significant changes in the rhythm of  $\text{Ca}^{2+}$  transient release and reabsorption regarding CON on day 2. As the treatment time prolonged, the

**FIGURE 4 |** Overview of altered m6A-tagged transcripts landscape in NRCMs with or without CYP. **(A)** The m6A dot blot assay was conducted in NRCMs after treatment with CYP or solvent control (CON) for 2 days. cardiomyocytes exhibited longer  $\text{Ca}^{2+}$  transient durations on day 4 and slower beating rate, lower  $\text{Ca}^{2+}$  release amplitude, and longer transient durations on days 6 and 8 (Figures 5B–D). We noted a similar pattern of changes in H9-GCaMP-CMs treated with 500 or 750  $\mu\text{mol/L}$

CYP at different time points. On days 2 and 4, compared with CON, CYP-treated H9-GCaMP-CMs exhibited lower  $\text{Ca}^{2+}$  release amplitude (Figure 5B) and longer transient durations (Figure 5D). Interestingly, in addition to lower  $\text{Ca}^{2+}$  release amplitude, slower  $\text{Ca}^{2+}$  transient durations

**FIGURE 5 |** hESCs-CMs treated with CYP exhibited abnormal  $\text{Ca}^{2+}$  handling properties. **(A)** Representative line-scan images in H9-GCaMP cell-derived cardiomyocytes treated with different concentrations of CYP at 2, 4, 6 and 8 days. Quantification of peak **(B)**, time to peak **(C)**, and calcium transient duration **(D)** in CON and CYP-treated H9-GCaMP-CMs. The data are shown as the mean  $\pm$  SE,  $n = 3$ . \* $P < 0.05$ , \*\* $P < 0.01$ , \*\*\* $P < 0.001$  vs. CON.

were observed to occur in H9-GCaMP-CMs treated with CYP at dose of 500 or 750  $\mu\text{mol/L}$  (Figures 5A,D). On day 8, compared with CON, H9-GCaMP-CMs treated with

low, medium and high concentrations of CYP exhibited lower  $\text{Ca}^{2+}$  release amplitude, and longer time to peak and transient durations (Figures 5A–D). These observations

**FIGURE 6 |** CYP induced the downregulation of JPH2 expression through upregulating METTL3 expression. **(A)** Western blot analyses of METTL3, METTL14, WTAP, FTO and ALKBH5 expression in NRCMs with or without CYP for 2 or 4 days. The data are shown as the mean  $\pm$  SE of three experiments. \**P* < 0.05, \*\**P* < 0.01 vs. CON. Real-time PCR analysis of METTL3 **(G)** and JPH2 **(H)** expression in NRCMs transfected with si-METTL3, or NC sequences with/without CYP. CYP did not decrease the expression of JPH2 in METTL3-deficient NRCMs. The data are shown as the mean  $\pm$  SE of three experiments. \*\**P* < 0.01; \*\*\**P* < 0.001 vs. negative control (NC).

indicated that CYP could induce abnormal electrophysiological and contractile alterations in cardiomyocytes, consistent

with the findings of the RNA sequencing and clinical data.

## CYP Inhibited JPH2 Expression by Modulating the m6A Writer METTL3

To understand whether m6A RNA methylation plays an important role in the suppression effects of CYP on JPH2 expression in NRCMs, we further investigated the effect of CYP on m6A writers (METTL3, METTL14, and WTAP) and erasers (FTO, and ALKBH5) in CYP-treated cardiomyocytes. Intriguingly, exposing NRCMs to different doses of CYP (250, 500, and 750  $\mu\text{mol/L}$ ) for 2 or 4 days resulted in a significant increase in the expression of METTL3 (**Figures 6A,B**), whereas the expression of METTL14, WTAP, FTO, and ALKBH5 was not significantly altered (**Figures 6A,C–F**). Similar results were observed in rats treated with CYP. The RNA level of METTL3 increased in hearts (**Supplementary Figure 6**). These results suggested that CYP induces the m6A methylation of JPH2 mRNA through increasing METTL3 expression, leading to downregulation of JPH2 expression.

To investigate the biological effect of METTL3 on the reduction of JPH2 expression, we designed small interfering RNAs to silence METTL3 in NRCMs. Intriguingly, silencing METTL3 (**Figure 6G**) resulted in an increase in JPH2 expression (**Figure 6H**). Additionally, CYP induced JPH2 downregulation in NRCMs transfected with NC sequences. However, there was no reduction effect of CYP on JPH2 expression in si-METTL3 cardiomyocytes (**Figure 6H**). These data indicated that CYP decreased JPH2 expression by upregulating METTL3.

## Disruption of METTL3 Eliminated CYP-Induced Electrical Alterations of Cardiomyocytes

To determine whether the disruption of METTL3 affects cardiac electrical and mechanical alterations in cardiomyocytes, we performed MEA in si-METTL3 and NC cardiomyocytes treated with CYP. Compared with NRCMs treated with NC, the FPD increased in NRCMs treated with CYP for 1 day (**Figure 7A**), whereas knock out of METTL3 significantly eliminated the increased FPD induced by CYP (**Figure 7A**). Similarly, the MEA results showed that the action potential duration (APD) (**Figure 7B**) was prolonged in NRCMs treated with NC after CYP treatment for 1 day (**Figures 7C,D**). However, the prolonged APD did not occur in si-METTL3 cardiomyocytes treated with CYP compared with the NRCMs treated with solvent control (**Figures 7C,D**). The above results demonstrated that the disruption of METTL3 eliminated the electrical alterations of cardiomyocytes induced by CYP.

## DISCUSSION

CYP is strongly correlated with cardiac electrical and contractile alterations (3, 40, 41). This study found that CYP was associated with QT prolongation, a decrease in E-C coupling efficiency, and cardiac contractile dysfunction. Specifically, our findings demonstrated that CYP induced RNA m6A modification by upregulating METTL3 expression and suppressing JPH2 expression (**Figure 8**). These results suggested novel therapeutic and preventive targets for CYP-induced cardiotoxicity.

CYP is widely used as an antineoplastic and immunosuppressive agent. The cytotoxic effect of CYP is induced by its biologically active metabolites (4, 42). CYP decomposes into acrolein and phoramide mustard (43), which further produces an unstable cation that may attack guanine bases (4), resulting in methylated bases. These DNA methylations lead to mutations and pair mismatches linked with its therapeutic effects on tumor cells. In fact, alkylating agents cause various DNA alkylation lesions including base methylation (9), which also induce RNA methylation. In our study, total m6A levels significantly increased in NRCMs after CYP treatment. Our experimental results showed that the m6A writer METTL3 significantly increased in cardiomyocytes treated with CYP, leading to an increase in m6A methylation of JPH2 mRNA. Promotion of the upregulation of METTL3 expression by CYP needs further exploration, however, the results suggested that RNA methylation played an important role in CYP-induced cardiotoxicity.

Previous study highlighted that CYP induced cardiac apoptosis when administered at a high dose (44), because the metabolite of CYP acrolein could promote the formation of reactive oxygen species (ROS) (45, 46). Hence, some studies have aimed to inhibit reactive oxygen-generators and regenerate other antioxidants that could prevent or treat CYP-induced acute cardiotoxicity (47). In this study, no myocardial death occurred in rats after treatment with CYP. We also observed no significant effect on the viability of cardiomyocytes in NRCMs treated with CYP at high concentrations. However, ANP and BNP both increased in cardiomyocytes treated with CYP, consistent with the findings of a previous study that showed CYP could induce cardiac hypertrophy (44). In this study, there was no obvious ventricular wall thickening in the ultrasound results owing to the short duration of CYP treatment in rats and administration being performed only once. However, increased ANP and BNP levels suggest that the molecular pathological changes may precede structural changes and the prolonged CYP treatment is required for organic changes to occur. Meanwhile, we found cardiac electrical alterations and decreased E-C coupling efficiency in rats after CYP administration. Although FS and LVEF did not decrease to heart failure in rats treated with CYP, these results were a 1-time consequence of CYP treatment with normal doses. Although prolonged QT and QTc interval, as well as E-C coupling time courses would recover after 3 days of administration, our results have implications for some patients with potential risk of ECG abnormalities during therapy for cancer and immune diseases. Interestingly, our data showed that CYP induced cardiac prolonged QT intervals and electromechanical coupling time courses accompanied by the downregulation of JPH2 expression. Calpain hydrolyzes JPH2 at the protein level (48), but CYP-induced decrease in JPH2 expression initiated from the RNA level in this study. To verify whether CYP-induced downregulation of JPH2 expression is mediated by miR-24 (31) and miR-331 (35), we further explored the effect of CYP on the biogenesis of the two miRNAs. There were no increases in the effect of CYP on miR-24 and miR-331, suggesting other regulatory mechanisms for JPH2. Interestingly, our subsequent results showed that m6A RNA methylation was associated with decreased expression of JPH2. These results

**FIGURE 7 |** Disruption of METTL3 expression eliminated the increased field potential duration (FPD) and action potential duration (APD) induced by CYP in cardiomyocytes. **(A)** Silencing METTL3 expression eliminated the increase in FPD induced by CYP. **(B)** Schematic of APD by the MEA processing of cardiomyocytes. **(C)** Representative images of APD in NRCMs transfected with si-METTL3, or negative control (NC) sequences with/without CYP. **(D)** Quantification of APD in NRCMs transfected with si-METTL3 or NC sequences with/without CYP. Silencing METTL3 expression eliminated the increased APD induced by CYP. The data are shown as the mean  $\pm$  SE of three experiments. \*  $P < 0.05$ ; \*\*  $P < 0.05$  vs. NC.

suggested that the increase in m6A of JPH2 mRNA is a novel mechanism in CYP-induced cardiotoxicity.

To investigate the mechanisms underlying of CYP-induced cell toxicity, we performed RNA sequencing to explore the potential targets and pathways. Our results showed that these DEGs were enriched in the biological process categories of leukocyte, lymphocyte and T cell-mediated immunity,

which corresponded to a recent study that CYP actively recruited macrophages into the bone marrow and eliminated drug-resistant malignant tumor cells (49). However, whether the positive regulation of immunity induces cardiac injury requires further study. These DEGs enriched in molecular function categories of phosphatidylinositol biphosphate, phosphatidylinositol-4,5-biphosphate binding, ATPase activity,

**FIGURE 8 |** Schematic of CYP-induced cardiac electrical and mechanical alterations. CYP decreased JPH2 expression by upregulating METTL3 expression, leading to  $\text{Ca}^{2+}$  transient irregularities and cardiac dysfunction.

and metal ion transmembrane transporter activity were associated with reduced ATP production and failure of  $\text{Ca}^{2+}$  transient in cardiomyocytes. According to this finding, the KEGG analysis showed that these DEGs were involved in the inflammation and calcium signaling pathways. Interestingly, we observed that cAMP signaling and the GnRH pathway were closely associated with the calcium signal and cardiac contraction (50, 51). The calcium signaling pathway was enriched in upregulated DEGs from MeRIP sequencing. In subsequent exploration of the effect of CYP on calcium signal, we found that CYP induces lower calcium release amplitude, and longer time to peak and transient durations. CYP-treated H9-GCaMP-CMs even exhibited lower calcium transient durations. These results are consistent with the adverse cardiac phenotype caused by CYP, suggesting that the calcium signaling pathway plays an important role in CYP-induced cardiotoxicity. Notably, the expression of JPH2, a key regulator for the  $\text{Ca}^{2+}$  influx and E-C coupling in cardiomyocytes (31, 52), significantly reduced after CYP treatment. Because decreased JPH2 is reportedly associated with atrial fibrillation (33) and arrhythmias (34), consistent with CYP-induced cardiotoxicity events, CYP-induced cardiac electrical and mechanical alterations may be closely related to the downregulation of JPH2 in this study. However, we cannot exclude other potential genes that play roles in regulating the process, such as paralemmin 2 (Palm-2), which upregulated m6A peaks and downregulated gene expression, was associated with cAMP-PKA signaling pathway, which has a strong influence on intracellular cation concentrations in the heart tissue or cardiomyocytes (53).

Previous epidemiological studies have suggested that prolonged QT intervals are closely associated with abnormal sodium, and potassium channels (54). However, the relationships between calcium ion binding protein imbalance and the pathological mechanism of QT prolongation are unknown. Recent studies have shown that  $\text{Ca}^{2+}$  binding proteins such as calmodulin (55, 56), and triadin (57), are associated with the long QT syndrome. These studies suggested that calcium plays an important role in the pathogenesis of cardiomyocyte repolarization and QT interval prolongation (58). JPH2 is the key regulatory protein that maintains a normal distance between LCCs and RyRs, which are important structures for  $\text{Ca}^{2+}$  release and recovery in cardiomyocytes. Moreover, a recent study demonstrated that the N-terminal part of JPH2

could bind and interact with caveolin-3 (59), which is a critical mediator for fixing LCCs on caveolar membrane in the plasma membrane and associated with long QT syndrome (60). Caveolin-3 is an important member of muscle-specific structural proteins of caveolae, which are also localized in T-tubules (61). These studies suggested that JPH2 interacts with caveolin-3 to mediate the junctional membrane complexes and  $\text{Ca}^{2+}$ -induced  $\text{Ca}^{2+}$  release in the cardiomyocytes (59). Although abnormal JPH2 expression decreases the fixation with caveolin-3, leading to disruption of the normal junctional membrane complexes and efficient  $\text{Ca}^{2+}$  transient, it may positively affect the QT interval. In this study, CYP induced the downregulation of JPH2 expression, resulting in increased FPD and APD in cardiomyocytes, which would be eliminated by silencing METTL3. Our results suggested that JPH2 aberration is closely related to the long QT syndrome. However, clinical data is warranted to determine whether the absence of JPH2 leads to the prolonged QT interval in future studies.

Despite these encouraging results, it is necessary to point out the limitations of this study. Silencing METTL3 increases the JPH2 expression, and JPH2 is not further downregulated in si-METTL3 NRCMs after CYP treatment. It is significant to use METTL3 knockout transgenic mice to verify whether CYP induced cardiac electrical and mechanical alterations by increasing m6A levels. Additionally, there are m6A methylation sites in both the 5'UTR and CDS of JPH2 mRNA, and the m6A methylation modification sites that regulate the expression of JPH2 need to be further clarified. Furthermore, the m6A levels and JPH2 expression abnormalities in CYP-induced cardiotoxicity should be confirmed in the clinic in future studies.

In summary, our results indicated that CYP-induced cardiac electrical and mechanical alterations and  $\text{Ca}^{2+}$  dyshomeostasis are associated with m6A methylation modifications and decreased JPH2. Our study found that CYP increased RNA m6A levels by altering METTL3 expression. Furthermore, decreased JPH2 expression plays an important role in CYP-induced cardiac electrical and mechanical alterations by blocking  $\text{Ca}^{2+}$  influx between transverse tubules and sarcoplasmic reticulum. Our findings demonstrated that RNA m6A methylation is a potential therapeutic intervention for CYP-induced cardiotoxicity.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE184294>.

## ETHICS STATEMENT

The animal study was reviewed and approved by the Ethics Committee of Peking University Health Science Centre (LA2021004).

## AUTHOR CONTRIBUTIONS

MX and MZ conceived and designed the experiments. MZ and YL performed experiments and acquired data. YS, SZ,

CH, XL, and FL provided materials. MZ, YL, and ZH performed data analysis. MZ, YL, and MX wrote the manuscript. All authors contributed to the article and approved the submitted version.

## FUNDING

This study was supported by the grants from National Natural Science Foundation of China (81625001 and 81900315) and the National Key Research & Development Program of China (2018YFC1312700 and 2018YFC1312701).

**Background:** The interplay between cancer and IE has become of increasing interest. This study sought to assess the prevalence, baseline characteristics, management, and outcomes of IE cancer patients in the ESC EORP EURO-ENDO registry.

**Methods:** Three thousand and eighty-five patients with IE were identified based on the ESC 2015 criteria. Three hundred and fifty-nine (11.6%) IE cancer patients were compared to 2,726 (88.4%) cancer-free IE patients.

**Results:** In cancer patients, IE was mostly community-acquired (74.8%). The most frequently identified microorganisms were *S. aureus* (25.4%) and Enterococci (23.8%). The most frequent complications were acute renal failure (25.9%), embolic events (21.7%) and congestive heart failure (18.1%). Theoretical indication for cardiac surgery was not significantly different between groups (65.5 vs. 69.8%,  $P = 0.091$ ), but was effectively less performed when indicated in IE patients with cancer (65.5 vs. 75.0%,  $P = 0.002$ ). Compared to cancer-free IE patients, in-hospital and 1-year mortality occurred in 23.4 vs. 16.1%,  $P = 0.006$ , and 18.0 vs. 10.2%;  $P < 0.001$ , respectively. In IE cancer patients, predictors of mortality by multivariate analysis were creatinine  $> 2$  mg/dL, congestive heart failure and unperformed cardiac surgery (when indicated).

**Conclusions:** Cancer in IE patients is common and associated with a worse outcome. This large, observational cohort provides new insights concerning the contemporary profile, management, and clinical outcomes of IE cancer patients across a wide range of countries.

**Keywords:** cancer, cardiac surgery, infective endocarditis, registry, valve disease

## INTRODUCTION

Infective endocarditis (IE) is a severe disease, associated with important morbidity and mortality (1–4). Some IE patients have active, previously diagnosed cancer. In other patients, IE might be a marker of a new, unsuspected neoplasia (5, 6). The interplay between cancer and IE has become of increasing interest (5, 7). Cancer patients may be at higher risk for IE, because of reduced immunity (e.g., due to antineoplastic therapy), central venous lines or portal catheters (8). Moreover, the clinical presentation of IE patients with cancer could be less specific. Additionally, therapeutic options might be limited, due to frailty and a potentially higher mortality risk in case of surgery.

The ESC EORP European Endocarditis (EURO-ENDO) registry is a multicentre, prospective, observational cohort study of IE patients at hospitals in Europe and ESC-affiliated/non-affiliated countries. The aim of EURO-ENDO is to investigate the care and outcomes of IE (9). This sub-analysis sought to assess the prevalence of cancer in IE patients and to determine baseline characteristics, management, and outcomes compared to IE patients that are free of cancer.

## MATERIALS AND METHODS

### Study Design and Data Collection

The detailed methodology of the ESC EORP EURO-ENDO registry has been previously reported (9). Briefly, from 1 January 2016 to 31 March 2018, patients older than 18 years who presented with IE were included. Inclusion criteria were a diagnosis of definite IE (or possible IE, but considered and treated as IE) based on the ESC 2015 IE criteria (10). IE patients with previously diagnosed cancer were identified. Cancer was defined as a previous or active, solid tumor, or hematologic malignancy. Data were collected at inclusion and during hospitalization, including demographics, patient history, Charlson index, age, and comorbidities (11). Moreover, data were collected concerning clinical, biological, microbiological, and echocardiographic findings, use of other imaging techniques [computed tomography (CT) scan, 18F-FDG PET/CT, leucocyte scintigraphy], medical therapy, complications, theoretical indications for surgery and in-hospital mortality (9). This study complies with the Declaration of Helsinki. National coordinators, in conjunction with local centers managed

the approvals of national or regional ethics committees or Institutional Review Boards, according to local regulations. Informed consent has been obtained from all subjects (or their legally authorized representative).

### Data Management and Statistical Analysis

Data were collected by the collecting officers at the participating sites and entered in an online electronic case report form (CRF). Data quality was monitored by the ESC EORP Registry Project and Data management teams. Data quality control followed a data validation plan defined by the Registry Executive Committee team in collaboration with the EORP team. The first author had full access to all the study data and takes responsibility for its integrity and the data analysis. Continuous variables are expressed as mean  $\pm$  standard deviation or as median and interquartile range. Comparisons among groups have been performed using Kruskal Wallis test for non-parametric data. Categorical variables are expressed as frequency and percentages. Among-group  $2 \times 2$  comparisons were made using Pearson's Chi-squared  $\chi^2$ -test or Fisher's exact test if any expected cell count was  $< 5$ . In other cases, the Monte-Carlo estimate of the exact  $P$ -value was used. Univariable analysis was applied to both continuous and categorical variables. Pairwise correlations between all candidate variables (variables with  $P < 0.10$  in univariable) within the model were tested before proceeding to the multivariable model. In case of correlation, some criteria were not taken into account. Plots of the Kaplan–Meier curves have been used to assess survival and event-free survival. A backward multivariable Cox regression analysis has been performed to evaluate possible predictors of outcomes in cancer patients. A significance level of 0.05 was required to allow a variable to stay within the model. Some measures of model of fit have been considered: concordance and the Goodness of fit test proposed by May and Hosmer. In addition, the proportional hazard ratios assumptions were graphically verified with the Schoenfeld residuals test. All analyses were performed using SAS statistical software version 9.4 (SAS Institute, Inc., Cary, NC, USA).

## RESULTS

Three thousand and eighty-five IE patients were included (12). Three hundred and fifty-nine (11.6%) IE patients with cancer were identified and compared to 2,726 (88.4%) IE patients without cancer. IE was definite in 304/359 (84.7%) and possible in 55/359 (15.3%) cancer patients. The age of and most frequent types of cancer can be found in **Supplementary Table 1**.

**Abbreviations:** CHF, Congestive heart failure; COPD, Chronic obstructive pulmonary disease; CT, Computed tomography; IE, Infective endocarditis; MI, Myocardial infarction; MRI, Magnetic resonance imaging; TIA, Transient ischemic attack; TOE, Transoesophageal echocardiography; TTE, Transthoracic echocardiography.

## Patient Demographics and Characteristics

The main demographic and characteristics of IE cancer patients are displayed in **Table 1**. IE was community-acquired in 74.8% and healthcare associated in 25.2% (nosocomial in 18.6%, non-nosocomial in 6.6%), native in 209 (60.4%), prosthetic in 97 (28.0%), device-related in 30 (8.7%), and repaired valve IE in 23 (2.9%) cancer patients. There were no significant differences with the cancer-free group. Valvular IE location was aortic in 52.7%, mitral in 47.0%, tricuspid in 5.7%, pulmonary in 0.9% of IE cancer patients. IE affected two or more valvular locations in 17.9%.

## Clinical and Biological Features

Clinical features are displayed in **Supplementary Table 2**. For IE cancer patients, significantly less time passed between first symptoms and first hospitalization ( $23.7 \pm 46.4$  vs.  $30.1 \pm 70.6$  days;  $P = 0.009$ ), as well as between first hospitalization and suspected IE ( $9.1 \pm 20.1$  vs.  $9.2 \pm 42.5$  days;  $P < 0.001$ ) compared to IE patients without cancer. Platelets were significantly lower in the IE cancer group ( $194.5$  vs.  $214$  K/mm<sup>3</sup>,  $P < 0.001$ ), but otherwise there was no significant difference in biochemistry between groups (data not shown). Blood cultures were positive in 303/359 (84.4%) IE cancer patients (vs. 78.4%,  $P = 0.009$ ). The most frequently identified microorganisms were *S. aureus* in 77/303 (25.4 vs. 31.8%,  $P = 0.024$ ), Enterococci in 72/303 (23.8 vs. 14.8%,  $P < 0.001$ ), and Streptococcus gallolyticus in 33/303 (10.9 vs. 5.9%,  $P = 0.001$ ) IE cancer patients.

## Imaging

Transthoracic echocardiography (TTE) was performed in 93.9% and transoesophageal echocardiography (TOE) in 82.2% IE cancer patients. There were significantly more mitral valve vegetations (39.9 vs. 34.8%,  $P = 0.020$ ), but less tricuspid valve vegetations (5.3 vs. 10.5%,  $P = 0.008$ ) in IE cancer patients. No significant difference in vegetation length was found between IE cancer and cancer-free groups (data not shown).

18F-FDG positron emission tomography/computed tomography was performed in 74 (20.6%) and positive in 55 IE cancer patients. There was 69.1% extra-cardiac uptake, vs. 54.3% in cancer-free IE patients ( $P = 0.042$ ). On multislice CT, there was significantly more perivalvular abscess formation in IE cancer compared to cancer-free IE patients (78.6 vs. 50.5%,  $P = 0.049$ ).

## In-hospital and One-Year Follow-Up Under Treatment

The main in-hospital complications are shown in **Supplementary Table 3**.

Acute renal failure was the most frequent in hospital complication in IE cancer patients, followed by embolic events and congestive heart failure (CHF).

After 1 year, there was no significant difference in IE recurrence rate ( $P = 0.243$ ) or other complications between groups.

Cancer IE patients were significantly more treated with amoxicillin (35.8 vs. 26.3%;  $P < 0.001$ ), ceftriaxone (36.3 vs. 31.1%;  $P = 0.047$ ) and daptomycin (15.2 vs. 10.6%;  $P = 0.010$ ),

but less frequently treated with vancomycin (34.6 vs. 44.9%,  $P < 0.001$ ) compared to cancer-free IE patients.

Following ESC guidelines, theoretical indication for cardiac surgery was not significantly different between both groups (65.5 vs. 69.8%,  $P = 0.091$ ), but was effectively less performed when indicated in IE cancer patients during hospitalization (65.5 vs. 75.0%,  $P = 0.002$ ). The most frequent surgical indication in both groups was infectious (57.4 vs. 64.9%,  $P = 0.018$ ). Reasons for not performing surgery in IE cancer patients were most frequently the surgical risk (80.2 vs. 54.0%,  $P < 0.001$ ), death before surgery (17.3 vs. 22.9%,  $P = 0.260$ ) and patient refusal (16.0 vs. 19.3%,  $P = 0.486$ ), among others.

Death occurred in hospital in 84 (23.4 vs. 16.1%,  $P < 0.001$ ) and at 1-year follow-up in 43 additional IE cancer patients (18.0 vs. 10.2%;  $P < 0.001$ ). Causes of all-cause in-hospital and 1-year mortality are reported in **Tables 2, 3**, respectively. Predictors of in hospital and 1-year mortality by univariate Cox regression analysis can be found in **Supplementary Tables 4, 5**, respectively. Predictors of in hospital and 1-year mortality by multivariable analysis in IE cancer patients are shown in **Table 4** and **Supplementary Table 6**, respectively.

Kaplan-Meier survival curves for in hospital and 1-year all-cause mortality according to cancer and adjusted for surgery are shown in **Figures 1, 2**.

## DISCUSSION

The following key findings arise from the EURO-ENDO analysis regarding cancer in IE patients: 1. Cancer is common in IE patients with a prevalence of 11.6%. 2. IE cancer patients are significantly older, receive more long-term immune-suppressive treatment and have more IV catheters. 3. The most frequently identified microorganisms are *S. aureus* and Enterococci. The source of infection is mainly community-acquired and preceded by non-dental procedures. 4. In hospital and long-term mortality is significantly increased and often related to the neoplasia. 5. Theoretical indication for cardiac surgery is not significantly different, but surgery is significantly less performed when indicated in IE cancer patients compared to IE patients without cancer.

## Demographics, Clinical and Microbiological Characteristics of IE Cancer Patients

Cancer is common in IE patients, with a prevalence of 11.6%. Preceding studies have shown a similar prevalence ranging from 5.6 to 17.6% (6, 8). Prostate- and intestinal neoplasms were found most frequently, which is consistent with previous reports (6, 7). The older age of IE cancer patients has been consistently reported in other series (6, 8, 12). IE cancer patients were more often males, as in the cancer-free group. One study found a slightly significant male predominance in IE cancer patients (6), while another was in agreement with this cohort (8). No gender-based differences were found.

IE cancer patients more often had a history of arterial hypertension, ischemic disease, aortic valve stenosis, atrial

MI, Myocardial infarction.

fibrillation and previous stroke, probably due to older age. There exists an overlap between cancer and cardiovascular disease, with shared biological mechanisms, risk factors and genetic predisposition (13). Cancer patients had a less typical clinical presentation with significantly less fever and new heart

murmur compared to cancer-free IE patients. Nevertheless, cancer patients were hospitalized and diagnosed significantly faster, probably due to close follow-up care. There was no significant difference in embolic events at admission between groups, despite significant more antithrombotics use in IE cancer

patients. This was probably compensated by the older age and prothrombogenic status in the cancer group.

IE could be a consequence of cancer management, as immunosuppressive therapy, intravenous access and portal

catheters were significantly more present in the IE cancer subpopulation, as previously described (6). Nevertheless, the source of infection was mainly community-acquired in this cohort, and comparable to the cancer-free population (74.8 vs. 74.2%,  $P = 0.06$ ). In contrast, previous studies had reported increased nosocomial IE in cancer patients, but the reason for this discrepancy is unclear (6–8, 14). The most frequent preceding non-cardiac interventions performed in IE cancer patients within the last 6 months were non-dental: urogenital and intestinal (including colonoscopy), as previously reported (6, 8). The significantly higher burden of enterococcal IE might be related to the portal of entry, but also to increased age, as seen in the general population (8, 15). As reported in previous studies, *S. aureus* remained the most frequent causative organism (6, 8). These results, combined with low oral Streptococci (8.9 vs. 12.9%,  $P = 0.05$ ) in blood cultures [compared to the general population in the EuroHeart Survey (15%) (16), the 2008 French registry (20.6%) (10), and the International Collaboration on Endocarditis-Prospective Cohort Study (17%)

**TABLE 4 |** Multivariate Cox regression analysis for in hospital all-cause mortality (1-month period) in IE cancer patients.

	Hazard ratio	95% CI	P-value*
Creatinine > 2 mg/dl	2.34	[1.29–4.25]	0.005
Chronic Heart Failure	2.16	[1.18–3.95]	0.013
Surgery: Indication – not performed	2.41	[1.20–4.81]	0.013
Surgery: Indication – performed	0.56	[0.25–1.24]	0.151

Goodness of Fit test:  $P = 0.50$ . Concordance = 0.74 – Global Schoenfeld residual test  $P = 0.21$ .

\*P-value corresponds to the results of the Wald test. For indication – surgery performed, the reference is: no indication.

(3)], reinforce the recommendations of the 2015 ESC guidelines regarding the restriction of the use of antibiotic prophylaxis to high risk populations undergoing at-risk dental procedures (10). Conversely, there might be opportunities for IE prevention in invasive urogenital and gastrointestinal procedures in cancer patients (8).

About 16% of cancer patients had culture-negative endocarditis, which is lower than previously reported, but not significantly different compared to the non-cancer group (8, 17). In these cases, non-bacterial thrombotic endocarditis could not be ruled out.

## Imaging

The transformation in the use of imaging techniques observed in the EURO-ENDO population since the publication of the 2015 ESC guidelines was similarly applicable for IE cancer patients (12). 18F-FDG PET/CT showed more extracardiac liver uptake in IE cancer patients compared to non-cancer patients. Unfortunately, it's difficult to differentiate between metastatic lesions, inflammatory foci and embolic lesions related to IE.

## Management and Outcome of IE in Cancer Patients

### Surgery

Surgery was performed in ~50% of patients, similar to previous surveys (3, 16). Bioprosthetic valves were used in most IE cancer patients (aortic bioprosthesis: 76.3 vs. mechanical 14.0%; mitral bioprosthesis: 41.5 vs. mechanical 18.5%); more than in non-cancer patients (aortic bioprosthesis: 56.2%,  $P < 0.001$ ; mitral bioprosthesis: 37.2%,  $P = 0.003$ ) and much higher than observed in the Euro heart survey, in which mechanical prosthesis were more prominent (74%). This change might be related to older age, the possible need for further surgical procedures and to an increased risk of bleeding in some neoplasms (18). Mitral valve repair techniques were also more frequently used in cancer compared to non-cancer IE patients (40 vs. 23.4%;  $P = 0.003$ ). This might be explained by a selection bias in the IE cancer group that was accepted for surgery, with a lower operative risk and less valvular destruction (19). Indication for surgery during hospitalization was comparable in cancer vs. non-cancer IE patients. However, when indicated, cardiac surgery was

effectively less often performed in cancer compared to cancer-free IE patients. Patients of both groups were mainly denied because of high surgical risk or a significant delay leading to death before surgery.

## Complications

Acute renal failure was the most frequent complication, followed by embolic events and CHF in IE cancer patients. The older IE cancer group had significantly more underlying chronic renal failure.

There was a significant lower incidence of pulmonary embolism in cancer IE patients. This might be explained by reduced IV drug abuse and less tricuspid valve vegetations in the IE cancer group, as well as a higher proportion of antithrombotic treatment. Nevertheless, this was not reflected by a significant reduction in other embolic events between groups at admission or during hospitalization.

CHF and cardiogenic shock occurred significantly more frequently in IE cancer patients, possibly due to the presence of more cardiovascular disease and frailty in this older population.

## In-hospital and 1-Year Mortality

In-hospital and long-term all-cause mortality was significantly increased in IE cancer patients compared to the non-cancer population. However, there was no significant difference in cardiovascular death between groups. A main driver of all-cause mortality in cancer patients was the neoplasia, especially at 1-year follow-up. This might be explained by the necessity to interrupt the cancer treatment due to IE, as noted in previous studies (6, 8). Mortality was particularly elevated in the IE cancer group when surgery was indicated but not performed, emphasizing the need for early discussion with surgeons within the IE team, as recommended by the ESC guidelines (19).

## Study Limitations

This sub-analysis has the same inherent limitations as the EURO-ENDO registry, particularly selection bias as the majority of patients (88.2%) were enrolled in high-level centers in western Europe. Moreover, the study is unlikely to be a true population-based sample, as it was based on voluntary participation and thus it is unsure whether all centers included their patients consecutively and prospectively (12). As a consequence, the true prevalence of cancer in IE patients remains uncertain. As this study was selected from IE patients and not cancer patients, we are also unable to provide incidence data on IE in cancer patients. Moreover, all cancer types might not be appropriately represented, details are missing about cancer characteristics (history, stage, active, or previous treatment) and further investigations are warranted in the occurrence of IE in solid vs. non-solid (e.g., hematological) malignancies, as well as the proportion of metastatic cancer which could influence mortality (8). Moreover, the influence of cancer treatment cessation on mortality should also be taken into consideration. The reason for denial of surgery should be more thoroughly investigated in future studies of IE cancer patients. Clinical reasons could range from a high age, frailty, comorbidities, expected poor prognosis from the underlying malignancy to

significant immunosuppression which might render surgery either futile or risky. Moreover, the valvular heart disease guidelines are not specifically written for patients with co-existent malignancies.

As cancer plays a major ponderation in the Charlson score, a sub analysis using an adjusted Charlson score excluding cancer is merited. Additionally, data regarding the occurrence of newly discovered cancer in IE patients, e.g., colon cancer diagnosed by colonoscopy, is absent in this registry. It has been suggested that IE could be an early marker or consequence of occult cancer, particularly that of gastrointestinal or urinary origin (6, 7, 20). Finally, it would be of interest to relate preceding invasive procedures for different types of solid cancers to the bacterial etiologies of IE. These limitations were counterbalanced by the high number of enrolled patients, the quality of CRF completion, and representation of a wide range of both university and non-academic hospitals in many countries around the world.

## CONCLUSION

This is a large, observational cohort of IE patients with cancer. It provides new insights concerning the contemporary profile, management and clinical outcomes of IE cancer patients. Given the paucity of randomized and large-scale observational data in IE patients with cancer, this registry offers a unique perspective on the current care of IE cancer patients across a wide range of countries.

With the development of anti-tumor drugs, tyrosine kinase inhibitors (TKIs) are an indispensable part of targeted therapy. They can be superior to traditional chemotherapeutic drugs in selectivity, safety, and efficacy. However, they have been found to be associated with serious adverse effects in use, such as myocardial infarction, fluid retention, hypertension, and rash. Although TKIs induced arrhythmia with a lower incidence than other cardiovascular diseases, much clinical evidence indicated that adequate attention and management should be provided to patients. This review focuses on QT interval prolongation and atrial fibrillation (AF) which are conveniently monitored in clinical practice. We collected data about TKIs, and analyzed the molecule mechanism, discussed the actual clinical evidence and drug-drug interaction, and provided countermeasures to QT interval prolongation and AF. We also pooled data to show that both QT prolongation and AF are related to their multi-target effects. Furthermore, more than 30 TKIs were approved by the FDA, but most of the novel drugs had a small sample size in the preclinical trial and risk/benefit assessments were not perfect, which led to a suspension after listing, like nilotinib. Similarly, vandetanib exhibits the most significant QT prolongation and ibrutinib exhibits the highest incidence in AF, but does not receive enough attention during treatment.

**Keywords:** TKIs, QT prolongation, atrial fibrillation, molecule mechanism, therapeutic strategies, pharmacokinetics

## INTRODUCTION

Protein kinases are enzymes that catalyze adenosine triphosphate (ATP)  $\gamma$ -phosphate transfer to tyrosine residues of the substrate protein and regulate many essential cellular biochemical functions including differentiation, proliferation, and death (1). More than 500 kinases have been discovered, and depending on their substrate specificity, they can be divided into two categories: catalytic tyrosine/tyrosine-like phosphorylation and serine/threonine phosphorylation (2). More than 30% of proteins may be modified by the kinases in the human body (3) and over 50% of proto-oncogene and oncogene products have protein tyrosine kinase activity (4). In this way, tyrosine kinase inhibitors (TKIs) by competitive inhibition of the ATP binding pocket, inhibit tumor proliferation, which has been widely used in cancer target therapy (1, 5).

TKIs can be divided into monoclonal antibody drugs and small molecule TKIs. Monoclonal antibody drugs are mainly bound to unique epitopes on the extracellular matrix to regulate downstream signal transduction, thereby inhibiting the proliferation, invasion, and angiogenesis of tumor cells. Small molecule TKIs act by intracellular inhibition of phosphorylation (6). So, inherently, small molecule TKIs are less selective than monoclonal antibodies and may lead to more adverse effects (AEs).

After the first TKI drug imatinib was approved in the US in 2001, a total of more than 30 TKIs were approved by the FDA up to 2020 (7). Although all the approved TKIs can inhibit BCR-ABL1, they still have different targeted sites and distinctive potency and activity. First-generation TKIs, like imatinib, dramatically improved the 5-year survival from 11 to 90% in Philadelphia chromosome-positive chronic myeloid leukemia (CML) patients (8). Second-generation TKIs, such as nilotinib (9) and dasatinib (10), exhibited the ability to overcome imatinib resistance and a more rapid molecule response. Third-generation TKI ponatinib is the only drug that works against BCR-ABL1<sup>T315I</sup> mutation (11).

As successful as TKIs are, they still face some challenges, such as AEs caused by drug poor selectivity, drug resistance, and other reasons. According to the FDA's Adverse Effects Reporting System (FARES) database's cardiovascular (CV) toxicity section, TKIs were considered to be the suspected drug in 83.2% of CV events. And torsade de pointes/QT prolongation was considered the only acute event, which had a 6.8% incidence, higher than other anticancer drugs (1.4%) (12). Similarly, correlations were found between QT prolongation with increased risk of polymorphic ventricular tachycardia, which leads to lethal arrhythmia and subsequent sudden cardiac death (SCD) (3, 7, 12). The mechanisms and countermeasures of TKI-induced arrhythmia are still unknown. To this purpose, we wrote this paper to provide a broad overview for the potential of approved TKIs in prolonging QT interval and atrial toxicity and systemic and comprehensive treatment for patients.

As shown in **Figure 1**, the data for this review were identified by searches of PubMed and references from relevant articles using the search terms "TKIs," "QT prolongation," "atrial fibrillation," and "on and off-target." We identified 6,151 records through the PubMed database. We removed 2,759 records as they were review papers ( $n = 1,267$ ), meta-analyses ( $n = 1,181$ ), or case reports ( $n = 311$ ). A total of 2,931 studies on TKIs combined with other anticancer drugs were also removed. Then, 407 records were excluded by reading the abstract. Finally, 54 records were enrolled. Only articles published in English between 2005 and 2021 were included.

## POTENTIAL MOLECULE MECHANISM OF QT PROLONGATION AND ATRIAL TOXICITY

Most TKIs are multi-target drugs, and the target receptors include vascular endothelial growth factor receptor (VEGFR), BCR-ABL, platelet-derived growth factor receptor (PDGFR),

epidermal growth factor receptor (EGFR), and c-KIT, etc. (13, 14). Then they regulate the downstream signaling pathways, for example, PI3K, MEK, and AKT, etc. (14, 15). Only a few TKIs have only one or two targets, such as axitinib, bosutinib, and gefitinib (3). Due to the numerous targets of TKIs, the potential mechanisms of TKI-related side effects previously proposed can be divided into: "on-target" and "off-target" (14, 16) effects.

### On-Target

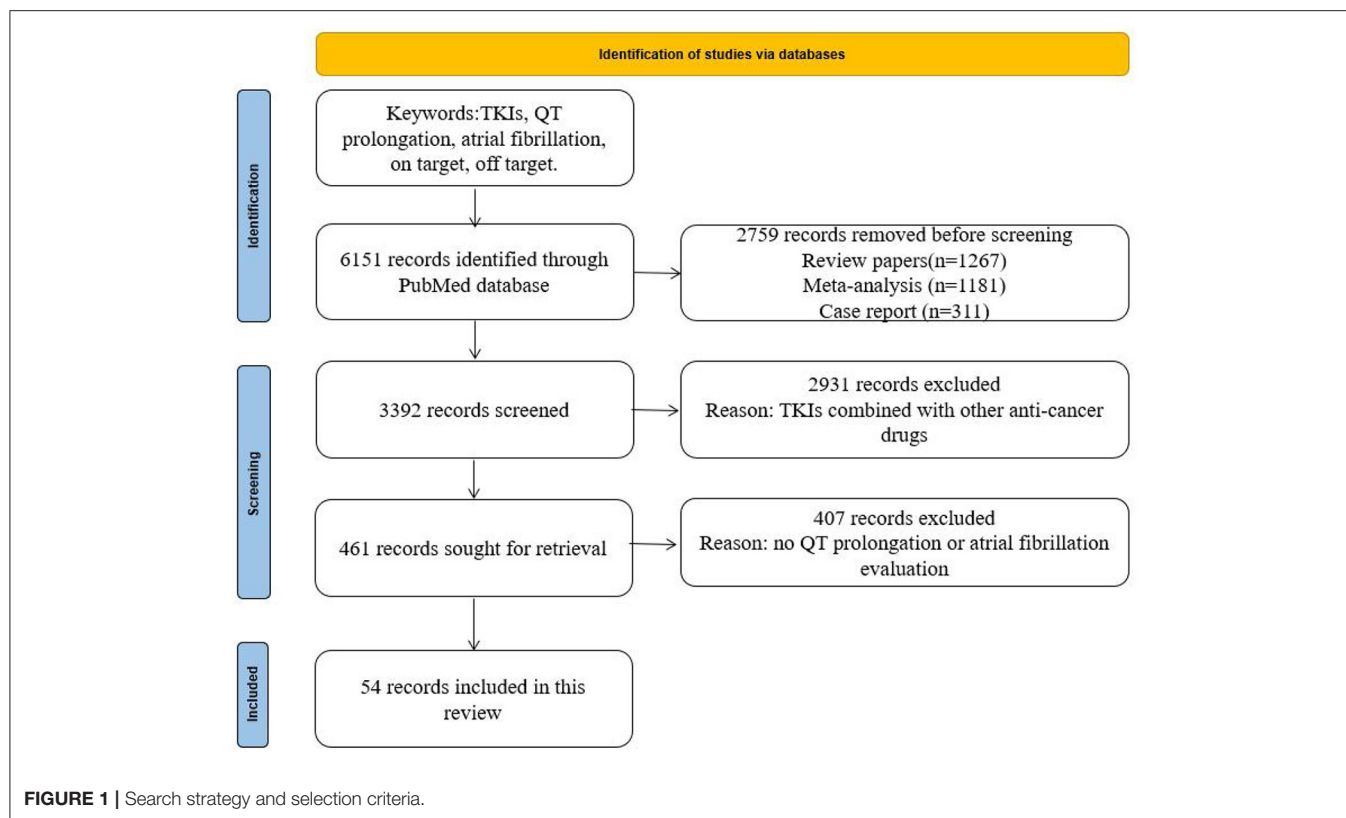

On-target means that the targets of TKIs exist in the tumor cell, but also play an important role in other normal organ cells, which may damage the biochemical function of normal cells (17, 18). A typical example of an on-target effect was observed in the Lu et al. trial. They designed an experiment to expose canine ventricular myocytes to drugs that have been demonstrated to prolong QT interval. As the result showed, the inhibition of the PI3K signaling pathway was the actual reason for QT prolongation. After blocking PI3K signaling, with the increase of persistent sodium current ( $I_{NaP}$ ) and the decrease of L-type calcium current ( $I_{CaL}$ ) and potassium current ( $I_{Kr}$  and  $I_{Ks}$ ), the total sodium and potassium current change accounted for over 70% of the whole prolongation, not just the potassium channels. And then, PI3K and its second message manager phosphatidylinositol 3,4,5-trisphosphate (PIP3) could affect multiple ion channels, similarly, resulting in action potential duration (APD). They also confirmed this result by breeding mice with reduced PI3K signaling showed QT prolongation (19).

Then, in McMullen's trial, they found that mice with decreased activity of the PI3K-Akt pathway was associated with higher susceptibility to AF and the same observation was relevant in humans. This pathway is an important regulator of cardiac protection under stress conditions. Other experiments also made a hypothesis that AF was related to ROS signaling, which would occur in abnormal  $Ca^{2+}$  release and atrial remodeling (20).

### Off-Target

Off-target refers to a non-selective TKI acting on normal organ cells. However, the target does not exist in tumor cells (21, 22). Generally, whether a TKI drug has the effect of QT prolongation, we can first observe whether there are fluorophenyl or fluoromethyl-phenyl rings in the molecular structure of the drugs (23). Drugs inhibit the hERG (human ether-a-go-go) subunit with which the channel conducts the main ventricular repolarization potassium current ( $I_{Kr}$ ) potential during phases 2–3 of the action potential (3, 24, 25). And hERG is regulated by cAMP and cAMP-dependent PKA. Vandetanib has been demonstrated to have values of hERG IC<sub>50</sub> of 0.4  $\mu$ M, and its metabolites are also active. In *in vivo* studies, a dose-dependent increase in QT prolongation has been demonstrated in dogs (3).

For instance, ibrutinib influences tumor cells by inhibiting Bruton tyrosine kinase (BTK); it also has off-target effects on Tec protein tyrosine kinase (TEC) (26). Both BTK and TEC transcripts have been demonstrated to express in cardiac tissue and at a higher expression when AF occurs rather than sinus rhythm. The PI3K-Akt pathway is regulated by BTK and TEC, and plays an important role in cardiac protection under conditions of stress (27).

Even if some drugs act on the same target or class of targets, it cannot be proved that these drugs have the effect of a prolonged QT interval. For example, sorafenib, vandetanib, and axitinib act on VEGFR, but only sorafenib and vandetanib will induce QT prolongation (23).

## SELECTED REPRESENTATIVE DRUGS

### Vandetanib

Vandetanib has the most significant prolongation of corrected QT interval according to Fridericia's formula (QTcF). It is an oral multitarget TKI drug, which inhibits VEGFR-2, EGFR, and the activity of tyrosine kinase. It was approved for the treatment of metastatic medullary thyroid cancer (MTC) by the FDA in 2011 (28).

In an early report, Ghatalia et al. initiated a meta-analysis about QTcF interval prolongation with VEGFR TKIs (29). They studied 13 clinical trials that included 4,204 patients with multi-tumor types who received 100 or 300 mg of vandetanib daily. The incidence of QT prolongation ranged from 0.3 to 23.9%, AF incidence ranged from 0.43 to 1.79%, and all-grade arrhythmia ranged from 0 to 1.69%. A high dose of vandetanib was associated with a high risk of QT prolongation by the authors. Then, under an approved dosage, phase II trial, multicenter, open-label study, 17 patients with metastatic or recurrent NSCLC with a RET rearrangement and against platinum-based doublet chemotherapy were treated with 300 mg of vandetanib once daily. A total of 6 out of 17 patients had grade 3 AEs, 2 were QT

prolongation (11%) (30). In another phase III, double-blind, placebo-controlled clinical trial, 331 patients with advanced or metastatic MTC were randomized 2:1 to receive 300 mg of vandetanib daily orally ( $n = 231$ ) or placebo ( $n = 100$ ). During the treatment, most AEs could be well-managed by dose interruption or reduction, QT prolongation occurred in 14 patients in all grades (31).

Vandetanib is metabolized by cytochrome P450 enzyme (CYP) 3A4, which inhibits or promotes activity by many common drugs (32). In a phase I trial, healthy individuals received 200 mg of itraconazole daily and were given a single dose of 300 mg of vandetanib on day 1 and day 4. A slight increase (9%) was observed in the serum concentration of vandetanib (33). Other substrates of CYP3A4, such as ketoconazole and rifampicin should be considered in the drug combination. In addition, other drugs which may induce QT prolongation need to be considered in the drug combination.

### Ibrutinib

Ibrutinib has the highest incidence of AF. It is an oral irreversible small molecule inhibitor of Bruton's tyrosine kinase (BTK), which is inhibited by a covalent bond with the specific cysteine Cys-481 of BTK, thereby inhibiting the proliferation and survival of malignant B cells, as well as reducing their migration and substrate adhesion (34, 35). Through the inhibition of BTK, downstream signaling pathways (MAPK, PI3K, and NF- $\kappa$ B) and phosphorylation functions (PLC $\gamma$ , ERK, and AKT) are influenced (35–37).

In a preclinical *in vitro* study, it was demonstrated that there were effects on hERG, but no specific risks for human cardiac issues, by the authors. In the *in vivo* safety study of dogs, ibrutinib may increase PR interval, decrease heart rate, and shorten heart rate-corrected QT interval (38). Besides, its use is associated with atrial toxicity. The possible mechanisms are still not entirely clear, but it has been demonstrated that AF is an off-target effect (39). Xiao et al., who used a mouse model and conducted chemo-proteomic analysis of cardiac lysates, found that C-terminal Src kinase (CSK) was the most likely target for ibrutinib-induced AF (40). Jiang et al. created a C57Bl/6 mice model where an ibrutinib group received 25 mg/kg/d of ibrutinib and a control group was treated with hydroxypropyl- $\beta$ -cyclodextrin for 4 weeks. Compared with the control group, the ibrutinib group displayed  $\text{Ca}^{2+}$  dysregulation in atrial myocytes, it increased spontaneous  $\text{Ca}^{2+}$  release, CaMKII level, phosphorylated CaMKII, and other related sites, and reduced sarcoplasmic  $\text{Ca}^{2+}$  capacity (41); both may lead to AF. Ibrutinib is an independent risk factor for the development of atrial arrhythmias, with an incidence of AF of more than 10–15% (42–44). Based on Alexandre's paper, ibrutinib is the most frequent anticancer drug to cause AF (45). In addition to straightforward arrhythmias, other potential effects of ibrutinib on ECG are little known. In early clinical trials, ~6–16% of participants had an increased risk of AF (46). A review of 16 studies showed that the incidence of ibrutinib-associated AF was 5.77 per 100 person-years (27). Fradley et al. enrolled 137 patients who were treated with ibrutinib, 21 pre- and post-ibrutinib ECG readings were obtained. Compared with the pre ibrutinib ECG, after administration, the ECG showed QT interval shortening from 446 to 437 ms, based on Bazett's formula (47). In another phase II clinical trial, a mean 7.5 ms shortening of the corrected QT interval was found after ibrutinib treatment (34). However, no significant QT effects were found in healthy subjects. Ibrutinib showed concentration-dependent mild shortening of the QT interval and PR prolongation, but seemed to have no significant clinical meaning (38).

Ibrutinib is metabolized by CYP3A4, therefore the coadministration of calcium channel blockers and other enzyme inhibitors should be fully considered. Besides, ibrutinib may increase the P-glycoprotein (P-gp) substrate level, such as digoxin and omeprazole, etc. (27, 48, 49).

## Ponatinib

Ponatinib is a third-generation TKI, which was designed by a computational and structure-based approach (50). It was created with a unique carbon-carbon triple bond linkage that overcomes the steric hindrance caused by the T315I mutant in CML or  $\text{Ph}^+$  acute lymphoblastic leukemia (ALL) (50, 51). The toxicity is mostly explained as a lack of selectivity, and on and off-target effects. Ponatinib inhibits over 60 kinases, including PDGFR, c-KIT, VEGFR, and EGFR. It also acts on perturbation of pro-survival signaling pathways, the AKT and ERK pathways impact cardiac function (52, 53). And in the Sharma et al. trial, they used human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) to evaluate the 21 approved TKIs, and demonstrated that ponatinib is the most toxic (54).

In a pre-clinical trial, ponatinib was not associated with cardiotoxicity. However, it exhibited a high occurrence of cardiac events in follow-up trials (11, 55). One year after being approved by the FDA, ponatinib was suspended because of safety concerns (56). At the dose of 50 mg/kg, the mean tumor volume decreased by 96%, so 45 mg once daily has been suggested, but the label cautions that an optimal dosage has not been identified (52, 57). In Sonnichsen's trial, 39 patients received ponatinib treatment at 30-, 45- and 60-mg dose levels, and the QTcF changes from baseline showed  $-10.9$ ,  $-3.9$ , and  $-5.0$  ms. Seventy-five patients in different dose levels were enrolled to evaluate the PK-PD effect, no significant correlation was found between drug exposure and QT changes (50). For the FDA CV events report for TKIs in 2020, 14.4% were found to be related to ponatinib (12). And in another clinical trial, 78 patients with CML were treated with ponatinib, the most common CAEs were arrhythmia (9%), higher than hypertension (7.7%) and myocardial infarction (3.8%) (58). In a ponatinib vs. imatinib phase III trial, 307 newly diagnosed CML patients were assigned to receive ponatinib ( $n = 155$ ) or imatinib ( $n = 152$ ). The results showed that no significant differences were observed in major molecule response at 12 months, but three serious AFs were observed in the ponatinib group, while no AFs occurred in the imatinib group (59).

Ponatinib is mostly metabolized by CYP3A4/5, but also by the substrates of CYP2C6 and CYP2C8. When co-administered with ketoconazole, the  $\text{AUC}_{0-\infty}$ ,  $\text{AUC}_{0-t}$ , and  $\text{C}_{\max}$  indicated increased exposures to ponatinib of 78, 70, and 47%, respectively. So, a dose decreased to 30 from 45 mg daily could be considered when combined with strong CYP3A4 inhibitors (60, 61).

## Nilotinib

Nilotinib also has strong cardiotoxicity. Its ability to prolong QT interval and induce AF is just after that of vandetanib and ibrutinib. It is an orally administered small molecule TKI that was designed with a lipophilic structure which competitively binds to the inactive conformation of the ABL kinase domain and leads to a higher and faster molecule response than imatinib in patients (62, 63). Nilotinib is more selective than imatinib, and does not have an effect on Src, EGFR, and VEGF kinase at a concentration  $<3,000$  nM (64–66). However, it targets PDGFR $\alpha$ , PDGFR $\beta$ , c-kit, DDR, and colony-stimulating factor receptor 1, which is similar to imatinib (65).

Under the multi-target effect, nilotinib induce cardiotoxicity. In a preclinical safety study, nilotinib inhibited the hERG channel at an  $\text{IC}_{50}$  value of  $0.13 \mu\text{M}$  (3), and exhibited the signs of QT prolongation in an isolated rabbit heart, but no toxicity in neonatal rat ventricular myocytes (67). There was no evidence that nilotinib had an effect on QTc in dogs at the dose up to 300 mg (3). In a response and safety phase I study, 33 patients with CML-BP were enrolled and received second-line nilotinib treatment. Thirteen patients (39%) achieved a hematologic response. As for arrhythmia, the QTcF increased by 5–15 ms in the study group, and one patient developed AF (grade = 2) (9). Then, in a phase II study, 280 patients with CML were enrolled, 6-month major cytogenetic responses were achieved in 48% of patients, and only 1% (3 of 280) had QTcF  $>500$  ms (62). In another phase II study, 44 patients with CML-AP

or CML-CP were enrolled, and 6.1% displayed QT prolongation at all grades (68). A positive correlation was found between QT prolongation and nilotinib exposure in many trials (69–71). In patients, as  $C_{\max}$  increased by 1,000 ng/ml, the QTcF also increased by 4.2 ms; an increase of 1,000 ng/ml in  $C_{\text{trough}}$  brought on an increase of 6.9 ms in QTcF (70, 71). Contrary to the earlier study, the 2020 FDA CV events report showed that QTc prolongation (any grade) induced by TKI was almost 28.8%, among these events 38.7% was due to nilotinib (12). It was significantly higher than early clinical trials. Alexandre et al. used the World Health Organization (WHO) individual case safety report database, vigibase, to identify the correlation between anticancer drugs and AF. As the results showed, 11,757 of 2,124,646 AF cases were associated with 176 anticancer drugs, and nilotinib accounted for 241 cases (2%) (45).

Nilotinib is also metabolized in the liver and is the competitive inhibitor of CYP3A4/5, CYP2C8, CYP2C9, CYP2D6, and uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1) (72, 73). When co-administered with ketoconazole, the area under the curve (AUC) increased by 3-fold and  $C_{\max}$  by 1.8-fold (74). Other drugs like rifampicin and esomeprazole reduced the plasma concentration to different degrees (72, 75).

## Dasatinib

Dasatinib seems to rarely cause QT interval prolongation events, and pooled safety data suggest that the overall risk for cardiotoxicity is minimal in dasatinib. But it still occurs in clinical use (76). Dasatinib is an effective BCR-ABL inhibitor in the treatment of CML and Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph<sup>+</sup> ALL) after relapse or resistance to imatinib (77, 78). It acts on the targets BCR-ABL, c-Kit, Src family kinases (SFKS), and PDGFR- $\alpha/\beta$ . By acting on BCR-ABL and the Src family, dasatinib inhibits the downstream PI3K signaling pathway (3, 79), which may induce cardiotoxicity.

The  $IC_{50}$  of the effect on hERG is 14.3  $\mu\text{M}$ , which is safer than vandetanib in QT effects. In an *in vivo* study, no QT prolongation was found in monkeys using a body-weight dose strategy (10 or 70 mg/kg). In a clinical trial, 2,182 patients were treated with dasatinib, 21 displayed QT  $\geq$  500 ms, all patients had a mean increase from baseline of 3–5 ms (3). In another retrospective study, 115 cancer patients received dasatinib treatment, 41.7% of patients showed QT prolongation and the mean (SD) of pre- and post-therapeutic QT interval change was 30 ms (12).

Dasatinib influences CYP3A4 and CYP2C8 enzymes and the drug transporter P-gp. In drug-drug interaction, omeprazole, esomeprazole, and pantoprazole will inhibit the P-gp to decrease absorption and lead to higher exposure. Metoclopramide has an additive effect on dasatinib which will increase the incidence of QT interval (80, 81). In a phase I PK and drug interaction study, 17 patients were enrolled to determine whether the coadministration of ketoconazole affected the PK of dasatinib (82). The result showed that ketoconazole led to an increase in dasatinib exposure and may correlate to an  $\sim$ 6 ms prolongation in QT interval.

The current study showed that QT prolongation occurred in nearly 30% of patients who received TKIs treatment, and 20% were high grade (7). Onco-cardiology is essential for cancer

treatment because the incidence of cancer and cardiovascular diseases (CVD) is concentrated in middle-aged and senior patients. During the cancer treatment, it may aggravate CVD, and its side effects may lead to failure of cancer treatment (6). Other unexpected side effects include: Human epidermal growth factor receptor 2 (HER2) and trastuzumab are associated with left ventricular ejection fraction (LVEF) decrease and congestive heart failure (CHF) (83); anti-VEGF drugs were found to significantly increase the incidence of hypertension (84). However, arrhythmia could be induced by lots of targets.

These five TKIs all have obvious characteristics, mechanisms, aim targets, and AEs. Vandetanib and ibrutinib were found to have high incidences of arrhythmia but dasatinib was recommended not to be much concerns about cardiotoxicity. All of them exhibit an effect on QT interval and atria toxicity in clinical application. And, according to the FDA and WHO databases, the impact of some TKIs in QT and AF is much higher than in previous clinical trials (12, 45). Although QT interval prolongation has a lower mortality than hypertension or coronary heart disease, it is convenient as a monitoring strategy of CVD, and evaluation of QT interval changes can maximize the optimization of drug cessation or reduction. The main information of the selected representative drugs is summarized in Table 1.

## MANAGEMENT

Arrhythmia induced by TKIs is easily monitored and can be an early warning of other serious CVD. For the agents with risk factors, routine monitoring methods such as ECG, blood pressure, electrolytes, and cardiac biomarkers are recommended during the course of treatment. In addition, collecting past medical history and physical function evaluation of patients are recommended to identify those at heightened risk for cardiovascular events. Once the arrhythmia occurs, beta-blockers and type I and III antiarrhythmic drugs are helpful for patients.

Primarily, CVD risk factors should be carefully evaluated before deciding to use TKIs. When patients are diagnosed with underlying diseases, like hypertension, coronary heart disease, diabetes, and other CVDs, they need to be carefully monitored based on their cardiac function. Baseline electrocardiograms (ECGs) should be obtained which will evaluate the risk of arrhythmia. Myoglobin (MYO), B-type natriuretic peptide (BNP), and other biochemical indexes should be obtained and corrected (85–87).

Second, electrolytes should be monitored, especially  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Ca}^{2+}$  which have an influence on heart rhythm. Abnormal electrolytes will be a potential risk of arrhythmia and should be corrected immediately (87, 88).

Third, drug-drug interaction should be fully considered. Most TKIs are metabolized by CYP enzymes and transported by P-gp; other drugs influencing CYP enzymes and the competitive bond to P-gp should be fully considered during coadministration. And drugs that have been proved to prolong the QT interval or induce AF should be avoided (89, 90).

**TABLE 1** | Target, effect on QT interval/AF, and metabolism of selected representative TKIs.

Name	Vandetanib	Ibrutinib	Ponatinib	Nilotinib	Dasatinib
Target	VEGFR-2; EGFR; RET	BTk; MAPK; PI3K	BCR-ABL; PDGFR; c-KIT; VEGFR; EGFR	BCR-ABL; PDGFR- $\alpha/\beta$ ; c-kit; DDR	BCR-ABL; c-KIT; SFKS; PDGFR- $\alpha/\beta$
Effect on QT interval	Prolong QT interval and with a positive drug exposure-dependent risk	Shorten QT interval	Prolong QT interval, no correlation was found between drug exposure and QT prolongation	Prolong QT interval with a positive correlation between exposure and risk	Rarely causes QT interval prolongation
Effect on AF	With a low incidence from 0.43 to 1.79%	Highest incidence of AF, nearly 10–15%	With a low incidence, about 1.29%	With a high incidence followed by ibrutinib	Rarely causes AF
Metabolized by	CYP3A4	CYP3A4	CYP3A4/5, CYP2C6, CYP2C8	CYP3A4	CYP3A4, CYP2C8

Fourth, reducing doses or stopping TKI treatment in time are of vital importance, especially when the QT interval is  $\geq 500$  ms, or the change of QT is  $> 60$  ms compared with baseline. TKIs could be restarted when the QT is  $< 450$  ms. If ventricular tachycardia, syncope, or other serious cardiovascular adverse reactions occurred again, the drugs should be stopped permanently (76, 91).

Fifth, after taking medicine, if a faint, headache, or irregular heartbeat occurs, healthcare should be provided immediately. The decision of heart rate or rhythm control should be patient-centered and symptom-oriented (87), beta-blockers may be the first choice for heart rate control, and type Ic and type III antiarrhythmic drugs are helpful for heart rhythm (87, 91).

## CONCLUSION

To conclude, we focused on the molecule mechanism, clinical outcome, coadministration, and countermeasures of TKI drugs in arrhythmia. There is commonality and variability coexistence in TKI class, studies showed that QT prolongation is the most significant in vandetanib, AF most occurs in ibrutinib, and nilotinib has a high incidence of QT prolongation and AF. Their actual incidence and life-threatening status are higher

than preclinical trials, lots of them do not get a black box warning from the FDA. But CVD caused by antitumor drugs needs to be avoided during treatment. Therefore, early diagnosis, convenient monitoring measures, and appropriate treatment methods should be provided to patients. So, ECGs monitoring should be more widely used in cancer patients, existing guidelines should be more specific, more real-world clinical trials need to be done, and on-target and off-target toxicity should be completely understood in the future.

## AUTHOR CONTRIBUTIONS

MC and FY collected data and wrote the paper. FY, JL, DY, SZ, and YY collected the literature and information. SJ, MD, and JL reviewed the paper. All authors read and approved the final manuscript.

## FUNDING

This work was supported by the Key Program of Harbin Medical University Cancer Hospital Haiyan Fund (no. JJZD2019-03) and the General Program of Harbin Medical University Cancer Hospital Haiyan Fund (no. JJMS2021-25).

Coronary artery reperfusion is essential for the management of symptoms in the patients with myocardial ischemia. However, the benefit of reperfusion often comes at an expense of paradoxical injury, which contributes to the adverse events, and sometimes heart failure. Reperfusion is known to increase the production of reactive oxygen species (ROS). We address whether N-acetylcysteine (NAC) reduces the ROS and alleviates reperfusion injury by improving the clinical outcomes. A literature search for the randomized controlled trials (RCTs) was carried out in the five biomedical databases for testing the effects of NAC in patients undergoing coronary artery reperfusion by percutaneous coronary intervention, thrombolysis, or coronary artery bypass graft. Of 787 publications reviewed, 28 RCTs were identified, with a summary of 2,174 patients. A meta-analysis using the random effects model indicated that NAC administration during or prior to the reperfusion procedures resulted in a trend toward a reduction in the level of serum cardiac troponin (cTn) [95% CI, standardized mean difference (SMD)  $-0.80$  ( $-1.75$ ;  $0.15$ ),  $p = 0.088$ ,  $n = 262$  for control, 277 for NAC group], and in the incidence of postoperative atrial fibrillation [95% CI, relative risk (RR)  $0.57$  ( $0.30$ ;  $1.06$ ),  $p = 0.071$ ,  $n = 484$  for control, 490 for NAC group]. The left ventricular ejection fraction or the measures of length of stay in intensive care unit (ICU) or in hospital displayed a positive trend that was not statistically significant. Among the nine trials that measured ROS, seven showed a correlation between the reduction of lipid peroxidation and improved clinical outcomes. These lines of evidence support the potential benefit of NAC as an adjuvant therapy for cardiac protection against reperfusion injury.

**Keywords:** N-acetylcysteine, coronary artery bypass, percutaneous coronary intervention, atrial fibrillation, antioxidants, reactive oxygen species, acute coronary syndrome, stable angina

## INTRODUCTION

A reperfusion injury has long been an unavoidable complication of the coronary artery revascularization procedures for the patients with acute or chronic myocardial ischemia. Although essential for the survival or for the relief of symptoms, reperfusion can contribute to as much as 40% of the final infarct size (1). The most common reperfusion procedure for the patients with myocardial ischemic is percutaneous coronary intervention (PCI). When reperfusion cannot be achieved successfully by PCI alone or in the setting of multivessel coronary disease, open heart surgery of coronary artery bypass graft (CABG) may be performed. Thrombolytic therapy can be prescribed during PCI, or alone when PCI and CABG are not readily available or impossible to perform due to the condition of a patient. One complication for each of these reperfusion treatments is periprocedural myocardial injury (PMI), which is linked to arrhythmias or reinfarction and in some cases heart failure. The release of massive amounts of reactive oxygen species (ROS) during reperfusion is thought to be an important cause of PMI.

Periprocedural myocardial injury is measurable with a number of clinical parameters, such as elevation of circulating cardiac troponins (cTn) or creatine kinase muscle band (CK-MB). Whereas, the amplitude or duration of cTn elevation can be predictive for the adverse events and heart failure (2–4), the extent of PMI is associated with the incidence of post-operative atrial fibrillation (POAF) (5). As a common complication following an open-heart surgery, the incidence of POAF can reach up to 70% in the patients after an elective CABG (6). POAF can cause stroke and increase the length of stay (LOS) in the intensive care unit (ICU) or in hospital. There is evidence supporting the concept that ROS and cytokine storm play a key role in the pathogenesis of POAF (7).

Despite a well-established association, ROS remains a neglected therapeutic target for the patients undergoing coronary reperfusion procedures. Administration of N-acetylcysteine (NAC) before reperfusion is expected to reduce the ROS generation. While a few randomized controlled trials (RCTs) showed a significant inhibition of cTn or CK-MB release or the incidence of POAF, other RCTs did not report positive outcomes. Given these inconsistencies, it is prudent to address whether NAC provides a benefit for the coronary reperfusion procedures through a systematic review and meta-analysis approach.

A few meta-analyses have assessed the cardioprotective effect of NAC during cardiac surgery (8–12). However, each of these reports has a limited number of references. More importantly, none of these reports have included consideration of PCI. About 90% of the patients with ST segment elevation myocardial infarct (STEMI) and 50% of the patients with non-STEMI are treated with PCI (13), supporting the importance of PCI when considering the benefit of NAC during reperfusion. Nevertheless, none of these published meta-analyses have determined the impact of NAC on all the common clinical measures, such as elevation of cTn or CK-MB, change in left ventricular ejection fraction (LVEF), and ICU or hospital length of stay (LOS). In addition, whether the clinical outcomes correlate with the

reduction of ROS has not been determined. Here, we address the cardioprotective effect of NAC when administered before PCI, CABG, or thrombolysis by summarizing the data from the publications with relevant clinical measures. In addition, the levels of antioxidants and ROS are captured to support the cause-effect relationship.

## METHODS

The Preferred Reporting Items for Systematic Reviews (PRISMA) guideline was adopted for this systematic literature review using an *a-priori* inclusion and exclusion criteria (14).

### Inclusion and Exclusion Criteria

*A-priori* inclusion criteria were: (1) the RCTs assessing the effect of NAC in the patients >18 years old who underwent coronary reperfusion by PCI, CABG, or thrombolysis; (2) NAC was administered within 24 h before or during coronary reperfusion; (3) the RCTs should have measured the effect of NAC in comparison to a control group; (4) the control group should have received either placebo or standard care; (5) the published manuscripts and abstracts for the RCTs; (6) the RCTs published in any language; (7) the RCTs should not have selectively included the participants with any degree of renal insufficiency; and (8) the RCTs published from inception to September 18, 2021.

We excluded those RCTs in which the effect of NAC was not compared with a control group, but instead was compared with another pharmacologic agent. In addition, we excluded those RCTs reporting the trials designed for the selective patients with renal insufficiency, since renal insufficiency itself causes increased levels of cTn and CK-MB (15), potentially underestimating the beneficial effect of NAC on cardiac injury.

We considered both the clinical cardiac endpoints and mechanistic measures in this systematic review. The clinical endpoints included biomarkers of myocardial injury (cTn and CK-MB), cardiac contractility (left ventricular ejection fraction, LVEF), infarct size, incidence of POAF, and postoperative ICU or hospital LOS. The mechanistic measures consisted of markers for total antioxidant capacity (TAC) and ROS. To reduce the complexity of the data, we only extracted the serum and urine levels of the non-clinical markers and excluded the measures from the biopsy samples.

### Literature Search and Data Extraction

A comprehensive search strategy was developed with the assistance of a health science librarian (Rachel Walden) using a combination of keywords and controlled vocabulary to identify the studies reporting the use of NAC in the patients undergoing coronary artery reperfusion with PCI, CABG, or thrombolysis. The search strategy was developed for PubMed/Medline (NLM) and was subsequently translated to carry out the searches in four other biomedical bibliographic databases: Embase (Elsevier), Web of Science (Clarivate Analytics), Cumulative Index to Nursing and Allied Health Literature (CINAHL), and Cochrane Library (Wiley). In addition to searching the five bibliographic databases, a search of the gray literature (Clinicaltrials.gov) was

performed. We searched for the trials from inception through September 18, 2021.

The following keywords were used to create the search strategy: myocardial reperfusion, T-Plasminogen activator, TPA, activase, alteplase, percutaneous transluminal coronary angioplasty, coronary balloon angioplasty, transluminal coronary balloon dilation, percutaneous coronary revascularization, percutaneous coronary intervention, PCI, coronary artery bypass grafting, CABG, aortocoronary bypass, coronary artery bypass surgery, coronary artery bypass, and acetylcysteine (as shown in **Supplementary Material** for full search strategy).

The primary (SAK) and the secondary reviewer (AMC) independently searched and screened the reports. Rayyan QCRI Systematic Reviews Web Application was used after careful removal of duplicate records (16). No major discrepancies were noted among the two independent reviewers in the shortlisted trials. The primary reviewer extracted the data and assessed the risk of bias for each RCT, while the secondary reviewer validated the data for each publication. Minor discrepancies were noted in the extracted data, which were resolved with discussion reaching a mutual agreement. The PRISMA flowchart summary is shown in **Figure 1**.

## Quality Assessment of Included Trials

The revised Cochrane risk of bias tool for randomized trials (RoB2) was applied by the primary and secondary reviewers to assess the risk of bias for each included trial [<https://methods.cochrane.org/bias/resources/rob-2-revised-cochrane-risk-bias-tool-randomized-trials> (2020, accessed 10 May 2020)]. The following domains were evaluated: random sequence generation, allocation concealment, blinding of patients and personnel, blinding of outcome assessment, and incomplete outcome data. Similar to the data extraction process, minor discrepancies in the risk of bias assessment were resolved through discussion for consensus generation.

## Statistical Analysis

The measurements in cTn, CK-MB, LVEF, and LOS were treated as the continuous variables with reported means and SDs, while the incidence of POAF was treated as a dichotomous variable. Instead of applying the fixed effects models, which operate under the assumption that the estimated effects across the studies were pulled from a single population, we employed the random effects models to calculate the pooled effects, as the true effect may derive from a distribution, due to the fact that multiple studies were

pulled from the different populations (17). The Sidik-Jonkman estimator was used for estimating the variance of the distribution of the true effect (18). The false positive rate increases when a small number of studies are enrolled and the outcome measures vary largely between the trials (19, 20).

In this NAC meta-analysis, the number of studies for each of six types of outcome measures varied from 5 to 12. Therefore, the Hartung-Knapp-Sidik-Jonkman method was also utilized to generate more robust estimates of the variance of pooled effects (19). When the outcome measures were continuous variables, the standardized mean difference (SMD) was calculated as a measure of effect size, as this is appropriate when different units were used across the studies (21). The SMD standardizes outcome measures in various units so that they are comparable at the same scale. Within a study, the SMD divides the mean difference of values of a measure by the pooled SD, thus SMD becomes a unitless standardized value. Hence, the SMDs can be compared across the studies for the related measures without the consideration of their respective units. The meta-analysis produces a pooled SMD, which denotes a change in the combined SD for a specific measure.

For dichotomous variables, relative risk (RR), a measure of effect size, was used as the likelihood of an event occurring between the two groups (NAC vs. control). The between-study heterogeneity was reported by  $I^2$ . The individual effect size for each study and its weight, as well as confidence interval (CI) for the individual studies and pooled estimates, were included in the results. All the statistical analyses were performed using R version 3.6 (<https://www.r-project.org/>) (2013, accessed 10 May 2020). Specifically, the meta-analysis was performed by the packages meta (22), metafor (23), and dmetar (24).

## RESULTS

### Characteristics of the Trials

**Figure 1** shows the PRISMA flowchart and the number of publications evaluated, leading to the selection of 28 trials in 32 publications for this systematic review (25–56). The characteristics of the included trials are summarized in **Table 1**. Geographically, the reported trials were carried out in 10 countries: Turkey (10), Iran (5), India (3), Germany (2), Uzbekistan (1), Czech Republic (1), Finland (1), Canada (1), Australia (1), Brazil (1), Korea (1), and China (1). The total sample size, by adding the number of patients in the final statistical analyses for each of the 28 included trials, was 2,174. Among the 26 trials with the gender and age distribution indicated as shown in **Table 1**, the mean age of the patients ranged from 53 to 71.5 years old. The two trials did not disclose the age distribution (30, 56).

N-acetylcysteine was administered *via* intravenous (IV) infusion in the 23 trials and the oral route (PO) in the 3 trials. The two trials administered NAC *via* both IV and PO. One trial did not report the route of NAC administration or dose (30). The dose of NAC ranged from 20 to 150 mg/kg in the 19 trials, and 0.3–4.2 g in nine trials (**Table 1**). NAC was administered during coronary reperfusion in the 16 trials, while 8 trials administered NAC within 30–120 min before the start

of reperfusion procedures. Four trials administered NAC the same day but before reperfusion procedure without specifying the timing (25, 28, 30, 34).

Among the 32 publications for the 28 trials included, 30 were journal articles and 2 were published abstracts. Twenty trials assessed the effect of NAC during CABG, five during PCI, two during thrombolysis, and one trial during PCI in combination with thrombolysis. Twenty-one trials had placebo controls, whereas seven practiced standard care in the control group. CABG was mostly elective for coronary artery disease, whereas the PCI and thrombolysis cases were urgent for acute coronary syndrome, except one trial where PCI was elective (39). All the included trials were published in English except one in Chinese (56), which was translated to English.

### Risk of Bias Analysis

The results from the risk of bias analysis are indicated in **Figure 2**. Each domain was assigned with a low, unclear, or high risk of bias score. Among the 28 included trials, low risk of bias was noted in the 25 trials, while some concern for risk of bias was noted in 3 trials as indicated in **Figure 2**. None of the trials showed a high risk of bias. Hence all the trials were included for the synthesis of final results.

### Effect of NAC Administration on the Clinical Outcomes

#### Serum cTn Elevation

Eight trials reported the means and SDs for the serum levels of either cardiac troponin I (cTnI) or troponin T (cTnT) following CABG or PCI (25, 33, 34, 40, 42, 46, 47, 49). The units of the measures are indicated in **Figure 3** legend. Two of the reports did not include units for troponin (34, 47). The inquiries to the authors of one report were not answered. A meta-analysis using SMD allows us to pool the values of cTnI and cTnT in a scaleless format into one analysis (57). This method does not require units for troponin. The means and SDs were extracted from each trial for the meta-analysis, with the form of troponin measured from each trial indicated in the figure legend (**Figure 3A**). Adding the enrollments from these trials yielded a total number of 271 for NAC and 262 for the control group. With a 95% CI, the pooled SMD was  $-0.80$ , with a range from  $-1.75$  to  $0.15$  ( $p = 0.088$ ). The value  $-0.8$  implies that cTn decreased by 0.8 times the pooled SD, which was 1.1, as a result of the NAC treatment when compared with placebo or standard care. This indicates a notable decrease in the cTn levels, even though the  $p$ -value for such decrease is 0.088, not significant but showing a trend. As expected, a high heterogeneity was observed across the trials ( $I^2 = 92\%$ ,  $p < 0.01$ ).

One trial was not entered into the meta-analysis due to reported median and interquartile ranges (IQR) for cTn, instead of means and SDs (43); hence, ineligible for grouping with the rest of the studies to perform the meta-analysis. This study used low dose NAC, 0.3 g, and did not indicate whether the reduction in the median cTn levels was significant due to NAC treatment [NAC group 4.8 (IQR 2.7, 6.0)] vs. control [5.5 (IQR 2.8, 6.4)]. Overall, our meta-analysis of eight trials suggests that there is a

trend toward the reduced levels of cTn in the NAC group when compared with the control group with 95% CI.

### Serum CK-MB Elevation

The means and SDs for the serum CK-MB concentrations were reported in 10 trials following CABG, PCI, or only pharmacological therapy (33, 34, 40, 44, 46, 47, 50, 51, 54, 55). With a meta-analysis using a 95% CI, we obtained a SMD value of 0.04, ranging from -0.43 to 0.50 ( $p = 0.861$ ) (Figure 3B). The heterogeneity was moderate across the trials ( $I^2 = 73\%$ ,  $p < 0.01$ ). One trial was not compatible for the meta-analysis,

due to reporting median and IQR instead of the means and SDs. This trial indicated no significant difference between the NAC and control groups [338 (IQR 290, 383) vs. 313 (IQR 260, 356)  $\mu\text{mol/L/h}$ ,  $p = 0.13$ ] (41). Overall, the NAC treatment had no significant effect on the procedure-associated elevation of CK-MB in the serum.

### Infarct Size

Three trials measured the infarct size after a coronary reperfusion procedure at 7 days (27, 41, 55). The infarct size was measured using cardiac magnetic resonance imaging (CMR) (27, 41) or

**FIGURE 3 |** Forest plots of random effects model meta-analysis with 95% confidence interval (CI) comparing NAcetylcysteine (NAC) group vs. control group. The plots are showing standard mean difference (SMD) for continuous variables along with standard deviations (SD) or risk ratio (RR) for binary variables along with events for **(A)** serum troponin levels at 24 h after procedure. Shafiei et al. (25) measured cTnI in ng/ml, Nozari et al. (33) measured high sensitivity TnT (hs-TnT) in ng/dl, Talasaz et al. (32, 34) measured hs-TnT (unit not available, inquires not answered), Kurian et al. (40) measured cTnI in ng/ml, Karahan et al. (49) measured cTnT in ng/ml, Prabhu et al. (42) measured cTnI in ng/ml, Peker et al. (46) measured cTnT in ng/ml, and El-Hamamsy et al. (47) measured cTnT in ng/l (per response to inquires). **(B)** Serum CK-MB levels, **(C)** left ventricular ejection fraction (LVEF), **(D)** post-operative atrial fibrillation (POAF), **(E)** length of stay (LOS) in intensive care unit (ICU), and **(F)** LOS in hospital.

electrocardiography (55). While one trial showed no significant difference [NAC group 17.4% (IQR 9.1, 25.9,  $n = 126$ ) vs. control group 14.3% (IQR 8.0, 26.2,  $n = 125$ ),  $p = 0.47$ ] (41), the two trials reported significantly smaller infarct size in the NAC vs. control groups [11% (IQR 4.1, 16.3,  $n = 53$ ) vs. 16.5% (IQR 10.7, 24.2,  $n = 59$ ),  $p = 0.02$ ; or  $16.3 \pm 10.5$ ,  $n = 14$  vs.  $24.4 \pm 9.5$ ,  $n = 16$ ,  $p < 0.05$ ] (27, 55). Furthermore, Pasupathy et al. (27) measured infarct size at 3 months and reported a significant reduction with the NAC treatment, with the infarct size in the NAC group being 5% on average (IQR 0.7, 12.4,  $n = 26$ ) compared with the control group, which was 10.2% (IQR 6.8, 14.8,  $n = 29$ ) ( $p = 0.02$ ). Overall, the two trials showed significant reduction of infarct size, while one trial showed no significant reduction; hence, the results are inconclusive with regard to whether or not NAC can reduce the infarct size.

### Left Ventricular Ejection Fraction

Left ventricular ejection fraction was measured within 7 days after coronary reperfusion in the five trials with a sum of 182 enrollments for NAC and 184 for the control group (26, 27, 42, 48, 55). The reported means and SDs were used for the meta-analysis (Figure 3C). With a 95% CI, the SMD was 1.25 with a range of  $-0.70$  to  $3.20$  ( $p = 0.150$ ). The heterogeneity was high across the trials ( $I^2 = 94\%$ ,  $p < 0.01$ ). Although the statistical results do not support that NAC had a significant influence on the LVEF, the distribution of means plus SMD value point to a trend of NAC benefit in improving the LVEF.

Not included in the meta-analysis were 4 trials, with a total enrollment of 442, due to reported median instead of means or the differences in time points of the LVEF measurements (27, 30, 41, 56). Nizomov et al. (30) measured LVEF at 1- and 3-month after PCI and indicated a significantly smaller number of participants with LVEF  $< 50\%$  in the NAC vs. control groups [11% vs. 16% at 1 month,  $p = 0.046$ , and 4% vs. 16% at 3 months,  $p = 0.017$ ], suggesting a benefit of the NAC treatment. Thiele et al. (41) reported that the median values of LVEF measured at 7 days were not significantly different [NAC 52.1% (IQR 43.5, 59.2) vs. control 50.6% (IQR 41.6, 58.6),  $p = 0.23$ ]. Pasupathy et al. (27) did not find a significant difference (NAC  $59.6 \pm 11.1\%$  vs. control  $56.7 \pm 10.5\%$ ,  $p = 0.33$ ) in LVEF measured at 3 months. Yang et al. (56) neither revealed the time point of measurement nor reported significant difference in LVEF between the NAC and control groups (57 vs. 53%, no SDs or  $p$ -values provided). Overall, the results are inconclusive based on the reported median values of LVEF.

### Post-operative Atrial Fibrillation

The incidence of POAF was reported in the 9 trials after CABG with a total combined patient number of 490 for NAC and 484 for control (26, 29, 35, 36, 38, 45, 47, 50, 53). It is known that POAF is a rare event following PCI, providing an explanation for the lack of POAF in the PCI trials. The number of patients developing POAF after reperfusion was registered either during the postoperative ICU stay or during the first 3 days of hospital stay. Using the binary outcome of the meta-analysis due to the report of events, we obtained the relative risk (RR) value of 0.57 with 95% CI, ranging from 0.30 to 1.06 ( $p = 0.071$ ). The

heterogeneity was low across the trials ( $I^2 = 35\%$ ,  $P = 0.14$ ). The meta-analysis points to a reduction, close to 50%, in the incidence of POAF with NAC treatment (Figure 3D).

### LOS in ICU

The nine trials reported the LOS in ICU with means and SDs for an added-up enrollment of 362 for the NAC group or 361 for the control group (26, 28, 29, 35, 38, 42, 49, 50, 54). The meta-analysis yielded SMD  $-0.38$  with 95% CI, ranging  $-0.91$  to  $0.15$  ( $p = 0.137$ , Figure 3E). The heterogeneity was high across the trials ( $I^2 = 81\%$ ,  $p < 0.01$ ). Although the meta-analysis results did not reveal a significant difference per 95% CI, there is a trend toward the reduction of LOS in ICU by the NAC treatment.

### LOS in Hospital

Hospital LOS with means and SDs were reported in 11 trials with a total enrollment adding up to 470 (NAC treated) or 468 (control) (26, 28, 29, 35, 38, 42, 45, 47, 49, 50, 54). The meta-analysis produced a SMD of  $-0.21$  with 95% CI, ranging  $-0.54$  to  $0.12$  ( $p = 0.180$ ), and high heterogeneity ( $I^2 = 70\%$ ,  $p < 0.01$ ) (Figure 3F). Similar to LOS in ICU, a trend toward the reduction in hospital LOS in the NAC group is shown by the upper boundary of the 95% CI close to 0.

## Effect of NAC on the Antioxidant Reservoir and ROS

Eighteen publications contained the measures for antioxidants and ROS, among which the nine trials had clinical outcome measures along with the lipid peroxidation product malondialdehyde (MDA). There is a lack of uniformity in the assays or time point of measurements between the studies, and most of the measures at a specific time point have less than five trials, which is not ideal for a meta-analysis. Nevertheless, for most of the measures, there was consistent reduction between the trials.

### Total Antioxidant Capacity (TAC)

Seven trials measured the antioxidant levels after the coronary reperfusion procedures (31, 37, 39, 40, 42, 44, 56) (Table 2). These studies reported the levels of antioxidants at the baseline and different time points after coronary reperfusion, from 10 min to 48 h. The measurements included reduced glutathione (GSH) or the activities of glutathione peroxidase, glutathione reductase, superoxide dismutase, and catalase in the serum. Two trials reported the outcomes as total antioxidant capacity (TAC) without specifying the scaled measures (37, 39). One trial measured the urine levels of TAC in addition to the serum levels (39).

The measurements of GSH between 1 and 12 h showed significant increases in the three trials (Table 2). No significant differences in the activity of glutathione peroxidase were observed, but there was a slight improvement in glutathione reductase in the 2 trials (Table 2). The data on superoxide dismutase and catalase are inconsistent among the 3 trials (Table 2). Ozaydin et al. (37) reported an improvement of TAC at 24–48 h after NAC, but not by Buyukhatipoglu et al. (39). The latter trial used a much lower dose of NAC (0.6 g, which

**TABLE 2 |** Total antioxidant capacity (TAC) after coronary artery reperfusion.

TAC: total antioxidant capacity, GSH: reduced glutathione, U/g: units per gram, Hb: Hemoglobin, mmol: millimole(s), nmol: nanomole(s).

translates to 0.01 g/kg per 60 kg body weight) than the average dose of 0.1 g/kg dose. Overall, there is evidence to support the possibility that the administration of NAC before a coronary reperfusion procedure leads to an increase of glutathione redox system activity as expected.

### Reactive Oxygen Species

Fourteen publications reported the levels of ROS markers after the coronary reperfusion procedures (25, 27, 31, 37, 39–42, 44, 48, 49, 52, 53, 56) (Table 3). The time points of measurements include the baseline and 15 min to 72 h after coronary reperfusion. The ROS was measured as MDA, myeloperoxidase (MPO) activity, oxidized glutathione (GSSG), advanced oxidation protein products (AOPP), or oxidized low density lipoprotein (LDL). The two trials reported the outcomes as the total oxidative stress (TOS) or total oxidant capacity (37, 39). All of these trials measured the serum levels of ROS markers except one trial, which also reported the urinary levels in addition to the serum levels (39).

Malondialdehyde was measured in the 9 trials, all of them showed significant reduction with the NAC treatment at different time points regardless of the reperfusion procedure performed, either PCI, CABG, or thrombolytic therapy (Table 3). MPO showed significant reduction in one trial but not the other (Table 3). Decreases of oxidized glutathione were observed in one trial (Table 3). Overall, there is evidence that the administration of NAC before the coronary reperfusion procedure significantly lowers the levels of ROS markers in the patients receiving NAC at various time points as compared with the control group.

### Correlation of ROS Reduction With the Clinical Outcomes

Table 4 compares NAC induced improvements in the TAC or ROS reduction with the clinical outcome measures. It is evident that a significant improvement of TAC or ROS reduction due to NAC correlates with the reduced levels of cTn, increased LVEF, and decreased LOS in ICU or hospital. Such correlation supports the cause-effect relationship of TAC or ROS with the improved clinical outcomes. This suggests that NAC might have mediated the improved clinical outcomes through the reduction of ROS.

### Sensitivity Analysis

We performed a sensitivity analysis to assess both the between-study heterogeneity and publication bias to ensure that the pooled effects for meta-analysis were indeed robust (58, 59). Between-study heterogeneity may be caused by a trial with either an extreme enrollment size or a larger impact on the pooled effect. To detect an influential trial, the Cook's distance, a well-established influential point detection method, was used (60). A trial may be considered as an influential case if the Cook's distance is  $>0.45$  (17). **Supplementary Figure 1** shows the Cook's distance for each measure in the meta-analyses, with the potential influential study highlighted in red. For cTn, CK-MB, or POAF, none of the trials have a Cook's distance over 0.45, indicating that there is no influential trial. For LVEF, LOS ICU, or hospital LOS, one potential influential study was detected, which is by Prabhu

et al. (42). To verify if the influential trial affects the summary data or the conclusion, we compared the results from the random-effects model with vs. without the influential trial. Removal of Prabhu et al. (42) trial reduced the heterogeneity for LVEF, LOS ICU, or hospital LOS, but did not improve the *p*-value or the direction of SMD (**Supplementary Table 1**), and therefore did not affect our conclusions.

Another potential issue for the meta-analysis is the publication bias due to the trials with a small sample size (17). We checked the small-study effects using the funnel plots, which display the relationship between the SMD of studies against its standard error (61). When there is no publication bias, the distribution of the trials in points (one point represents each trial) is symmetric and fits into the shape of an upside-down funnel. In the case of this NAC meta-analysis, a few trials landed outside the funnel area, but the asymmetry is not across all the different outcome measures (as shown in **Supplementary Figure 2**). Since visual inspection can be subjective, we performed the Egger's regression test (62) to evaluate the asymmetry quantitatively in the funnel plot for the continuous outcome measures, cTn, CK-MB, LVEF, LOS in ICU, and LOS in hospital, and Peters' regression test (63) for the binary outcome measure POAF. The results are shown in **Supplementary Table 2**. None of the statistical tests have a significance at the threshold of 0.05, suggesting that the funnel plots are roughly symmetrical. This indicates that the publication bias is not a major concern in the meta-analysis.

## DISCUSSION

The administration of NAC prior to the coronary reperfusion procedures was associated with a trend toward the inhibition of cTn elevation, reduced incidence of POAF, and lowered levels of ROS. The decrease of cTn by NAC treatment is considered notable due to the summary SMD being  $-0.8$  in reference to the SD of 1.1 from the meta-analysis of eight trials (**Figure 3A**). However, the overall *p*-value of 0.088 suggests that the decrease is close to 0.05 but not truly significant in the statistical analysis using 95% *CI*. While improvement in LVEF or reduction in ICU and hospital LOS were not statistically significant at 95% *CI*, the meta-analyses suggested a minor trend toward the improvement for these measures (**Figures 3C,E,F**). The effect of NAC on infarct size remains inconclusive due to the smaller number of trials. CK-MB represents the only outcome that did not show improvement with the administration of NAC. Given the fact that POAF is associated with older age and an increase in all-cause mortality (64), and whereas the level of cTn elevation predicts the incidence of adverse events and the risk of heart failure (2–4), adding NAC as an adjuvant therapy for reperfusion may provide benefit in these parameters. By decreasing these clinical complications, it could be expected that NAC administration might reduce the adverse events and the development of heart failure as well as possibly improving the long-term mortality.

An acute kidney injury (AKI) is often an additional complication of reperfusion procedures. We did not include this measure in our study due to the lack of such information in

n, indicates sample size; ROS, reactive oxygen species; TAC, total antioxidant capacity; cTn, cardiac troponin; CK-MB, creatine kinase muscle band; LVEF, left ventricular ejection fraction; POAF, post-operative atrial fibrillation; LOS, length of stay; ICU, intensive care unit; SOD, superoxide dismutase; GR, glutathione reductase; GSH, reduced glutathione; GPX, glutathione peroxidase; MDA, malondialdehyde; TOS, total oxidative stress. ↑ indicates increase. ↓ indicates decrease. ↑↑ indicates minor increase. ↔ indicates no change.

majority of the clinical trials on NAC for cardiac protection and the recently published systematic reviews with meta-analysis on the topic. Guo et al. (65) used the random effects model to evaluate the seven clinical trials for the effects of NAC on contrast-induced AKI in the patients with STEMI following PCI. This report showed a significantly reduced rate of AKI and all-cause hospital mortality with NAC compared with the placebo group (65). However, a meta-analysis of eight trials by Mei et al. using the random effects model for perioperative NAC among the patients with cardiac surgery concluded that there was no significant benefit in the prevention of AKI. The American College of Cardiology Foundation (ACCF) and American Heart Association (AHA) Guideline for Coronary Artery Bypass Graft Surgery noted the controversy surrounding the use of NAC for the prevention of CABG-associated AKI (66). However, the benefit of NAC as a potential intervention for POAF was not addressed.

Our data on POAF reduction with NAC are consistent with the published meta-analyses reporting the benefit of NAC for the patients with cardiac surgery. Two meta-analyses used the fixed effects model to determine the impact of NAC on POAF when administered before CABG among the eight trials, and showed a significant reduction of POAF (10, 12). In addition, the reduction of POAF was reported by Liu et al. (9), who summarized 10 publications (without the consideration of redundancy in trials) with meta-analysis using the fixed effects model. Wang et al. (11) registered seven trials for meta-analysis using the random

effects model and discovered a trend toward improvement in the incidence of POAF with NAC.

The additional clinical measures are less convincing for the benefit of NAC examining in our data and that of others. Pereira et al. (8), compiled 12 trials for meta-analysis with the random effects model and showed a trend but not statistical significance toward an improvement in the post-operative cardiac insufficiency, ICU LOS, or hospital LOS, and incidence of post-operative acute myocardial infarction or cardiac arrhythmias. Gu et al. (10) did not find that NAC reduced ICU LOS using a fixed effects model for a meta-analysis of four trials. Similarly, Liu et al. (9) did not find significant improvement or a trend toward the improvement of ICU or hospital LOS with five trials. Wang et al. (11) showed neither statistical significance nor a trend toward improvement in the incidence of acute myocardial infarction, the need for inotropic support, and ICU LOS, or hospital LOS with a random effects model meta-analysis of up to six trials. By consolidating the data from 10 trials, we observed a trend toward but not a significant reduction in LOS in ICU or hospital.

N-acetylcysteine is being used clinically for several decades. The main clinical uses for NAC to date include its mucolytic capacity in bronchi, as an antidote for acetaminophen toxicity, and as a protective agent against contrast-induced nephrotoxicity. NAC as a protective agent against reperfusion injury was first reported in 1992 by Sochman and Peregrin (6, 67, 68), who discovered total recovery of left ventricular

function after acute myocardial infarction when NAC was administered along with the coronary artery thrombolysis during the PCI. Multiple RCTs have been published since to address possible beneficial effects of NAC during the coronary artery reperfusion. Twenty-eight of these RCTs reviewed in this study revealed a trend toward the improvement in several clinical measures, with a correlation to reduction of ROS or lipid peroxidation. The correlation approach provides evidence for the mechanistic basis of the observed benefit of NAC.

## Strengths and Limitations

We have included three types of coronary artery revascularization procedures for the clinical practice, PCI, thrombolytics, and CABG. This differs from the other published meta-analyses, which focused on one type of reperfusion procedure. Additionally, we have evaluated the most common clinical measures, cTn or CK-MB, LVEF, POAF, and ICU or hospital LOS, and provided a correlation for the levels of antioxidants or ROS to the clinical measures. This differentiates our study from the other published meta-analyses.

The included RCTs were from multiple countries, with most trials having a placebo control. There were minimal losses to follow-up across the trials. The data were generated from multiple healthcare centers with multi-ethnicities due to a diverse distribution of recruitment among the different countries. Additionally, none of the RCTs presented here were funded by a for-profit organization and the risk of bias was low in most of the trials.

The negative factors affecting our analysis power include limited regions of the trials, sample size, gender distribution, and substantial heterogeneity. While there was no restriction on the country or language for trial inclusion, over 50% of the evaluated studies originated from Turkey (10 trials) or Iran (5 trials), and none of the trials were carried out in the United States. Although many factors may explain the uneven distribution for the trial origins, the genetic background in association with a unique region, and the differences in socioeconomic status for the healthcare provision may prohibit extrapolation of the findings to all case scenarios worldwide. Additionally, most of the included trials had an enrollment below 100 individuals. The participants were mostly middle-aged men, prohibiting the generalization to other age groups or female patients.

We have detected a large between-study heterogeneity in most of the outcome measures, with  $I^2$  varying from 35 to 94% (Figure 3). Several variables in the trials contributed to the substantial heterogeneity: (a) non-uniform coronary reperfusion procedures, with either PCI, CABG, or thrombolysis in different trials; (b) the dosage and the route of NAC administration differed among the trials, with three trials using the low doses of NAC, 0.3–0.6 g (39, 43, 44); (c) the patient populations carried distinctive diagnoses, from acute coronary syndrome requiring an emergency reperfusion procedure to stable coronary artery diseases treated with an elective reperfusion protocol; (d) a lack of information on timing from the onset of chest pain to

the reperfusion procedures. The large regional differences in such timing may affect the clinical outcome of reperfusion and NAC treatment; and (e) the healthcare facility and supportive infrastructure among the different countries or regions may influence the clinical outcome. If it had been possible to increase the sample sizes or reduce the heterogeneity, the statistical analyses would likely have yielded the  $p$ -values indicating significant differences supporting the benefit of NAC on multiple clinical outcome measures.

## Clinical Implications

Our findings suggest a trend toward the benefit of NAC treatment. The trend in the reduction of cTn suggests a potential reduction of cardiac injury by NAC. It is important to note that NAC, despite its low cost and multiple clinical implications already, is not free of side effects. Nausea and vomiting may be associated with an unpleasant odor during oral intake. For intravenous NAC, an anaphylactoid reaction occurs in 8.2% cases, such as cutaneous (acute flushing, pruritus, and rash) or systemic symptoms (bronchospasm, angioedema, hypotension, and chest pain) (69, 70). Additionally, NAC may have a negative impact on hemostasis in the patients under certain conditions. In a *post-hoc* analysis of an RCT of NAC in the patients undergoing cardiac surgery with an estimated glomerular filtration rate of  $\leq 60$  ml/min, administration of NAC (100 mg/kg IV bolus, followed by 20 mg/kg/h until 4 h after CABG) was associated with a greater blood loss and an increased need for transfusions (71). Therefore, the benefit of NAC remains to be fully established with larger controlled clinical trials measuring multiple clinical end-points. The risk vs. benefit analysis in such a trial would also be needed.

If well done, the RCTs with large numbers of patients were shown to be positive, then the addition of antioxidant therapy to the patients following reperfusion therapy or cardiopulmonary bypass would be a simple and inexpensive therapy. NAC, vitamin C, and other antioxidant agents are generic, inexpensive, generally safe, and would presumably be administered for a relatively short period of time, possibly hours to days. The long-term clinical implications of such therapy are not yet known and would need to be assessed.

## DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

## AUTHOR CONTRIBUTIONS

SK: study design, building search strategy for six electronic databases, acquisition of data, qualitative analysis, interpretation of data, writing and drafting the manuscript, and coordinating the project. AC: independently reviewed the literature and evaluated all the selected trials, validated the acquisition of data, provided input, and edit to the manuscript. YL: quantitative analysis and conducted meta-analysis. LA: supervising

statistician and manuscript editing. JA: a practicing cardiologist who helped with the clinical interpretation of the data, and manuscript editing. QC: initiated the conception, supervised the study, reviewed the literature, and revised the manuscript. All the authors edited and have approved this version of manuscript to be published.

## FUNDING

Research works under QC's direction are supported by NIH R01 GM125212, R01 GM126165, Holsclaw Endowment, and The University of Arizona College of Pharmacy start-up fund.

**Background:** There is a large amount of evidence that anti-angiogenic drugs are effective safe. However, few studies have evaluated the specific effects of anti-angiogenic drugs on myocardial enzyme injury biomarkers: aspartate aminotransferase (AST), lactic dehydrogenase (LDH), creatine kinase (CK) and creatine kinase isoenzyme (CK-MB). The purpose of our study was to determine whether anti-angiogenic drugs serum AST, LDH, CK, and CK-MB activities of cancer patients treated with anti-angiogenic drugs.

**Methods:** This study retrospectively analyzed 81 cancer patients. Patients who had used anti-angiogenic drugs were selected. Serum AST, LDH, CK, and CK-MB activities were measured before and after treatment with anti-angiogenic drugs for 3 weeks.

**Results:** A total of 16 cancer types were analyzed. The distribution of the cancer types in the patients was mainly concentrated in lung, gastric, and colorectal cancers. The anti-angiogenic treatment markedly increased AST, LDH, CK, and CK-MB activities by 32.51, 7.29, 31.25, and 55.56%, respectively in serum.

**Conclusions:** Our findings suggest that patients, who had used anti-angiogenic drugs were likely to have elevated AST, LDH, and CK, indicators of myocardial muscle injury. Use of anti-angiogenic drugs should not be assumed to be completely safe and without any cardiovascular risks.

**Keywords:** anti-angiogenic drugs, cancer, AST, LDH, CK, CK-MB

## INTRODUCTION

Anti-angiogenic treatment is an effective and targeted therapy strategy that can be used to control and kill tumors (1). Although chemotherapeutics can kill tumor cells, the remaining tumor cells can still survive and continue to grow due to the support of peripheral blood vessels. Meanwhile, abnormal tumor blood vessels reduce the delivery of drugs into tumor tissues, which ultimately leads to limited efficacy of anti-cell proliferation therapy. Therefore, the treatment for cancer should not only be directed against tumor cells, but also against the tumor microenvironment, in particularly tumor angiogenesis (2).

Vascular endothelial growth factor (VEGF) is the master effector of the angiogenic response in cancers (3). Anti-angiogenic drugs can be used to specifically bind to VEGF to prevent it from

interacting with receptors, which play a critical role in tumor blood vessels. Further, this limits exposure to oxygen and other nutrients required for tumor cell growth, thereby weakening the ability of tumor growth and metastasis. Anti-angiogenic agents targeting the VEGF and HIF- $\alpha$  pathways include monoclonal antibodies to VEGF (4), such as bevacizumab and resmumab, small-molecule tyrosine kinase inhibitors (TKIs), such as anlotinib, sorafenib, and sunitinib, and VEGF receptor (VEGFR)2 inhibitors, such as regorafenib and ramucirumab (5). These compounds can lead to a reduction in the tumor blood supply and growth of the tumor blood vessels. Unfortunately, cardiovascular toxicity is a potential limitation associated with the long-term use of anti-angiogenic agents in cancer and requires further study to assess the value of anti-angiogenic treatment.

Aspartate aminotransferase (AST) is a pyridoxal-5'-phosphate-dependent enzyme that is widely distributed in heart, liver, skeletal muscle, kidney and brain. It plays a key role in the metabolism of amino acids, synthesis of purine/pyrimidine bases, urea and protein synthesis, and gluconeogenesis (6). Lactic dehydrogenase (LDH) is a type of enzyme, which plays an important role in making body's energy. It can be found in almost all the body's tissues, including those in the blood, heart, kidneys, brain, and lungs. LDH is released from damaged tissues, and can serve as a biomarker for damaged heart tissue. Creatine kinase (CK) is a guanidino-kinase that catalyzes the reversible phosphorylation of creatine to phosphocreatine, and is primarily distributed in bone and myocardium. The plasma activity of creatine kinase isoenzyme (CK-MB), one of the isoenzymes of CK, is generally used to evaluate acute coronary syndrome. The detection of serum CK isozymes, especially serum CK-MB, is helpful for judging the degree of myocardial injury. Comprehensively, monitoring serum AST, LDH, CK and CK-MB activities for cardiac biomarkers can be valuable for assessing patient status (7, 8).

Unfortunately, few studies have focused on the measuring changes in serum AST, LDH, CK and CK-MB activities before and after anti-angiogenic treatment for cancer. In this study, we conducted a retrospective investigation focused on measuring the changes in serum AST, LDH, CK and CK-MB in serum on cancer patients receiving anti-angiogenic targeted therapy. The results suggested that in serum AST, LDH, CK and CK-MB activities of patients who had used anti-angiogenic drugs were likely to have elevated.

## MATERIALS AND METHODS

### Patients

This was an observational, retrospective study that obtained informed consent from all subjects, and this research was approved by the Ethics Committee of Guang'anmen hospital, China Academy of Chinese Medical Sciences with code number 2020-073-KT. The study followed the ethical principles of the Declaration of Helsinki 1964.

From Jan 2014 to Dec 2020, cancer 81 patients treated with apatinib, anlotinib, regorafenib, bevacizumab, sorafenib, or sunitinib at the oncology department, Guang'anmen hospital,

China Academy of Chinese Medical Sciences were retrospectively recruited for this study. Patients with active infection, systemic corticosteroid treatment within 1 year, or hematological malignancy were excluded since these conditions might affect the hematological laboratory markers. Meanwhile, 81 gender and age matched healthy control were enrolled from physical examination center, Guang'anmen hospital, China Academy of Chinese Medical Sciences.

### Data Collection

The following variables were extracted from the medical records of the patients: AST, LDH, CK and CK-MB results, age, gender, histological diagnosis, and the choice of anti-angiogenic drugs (such as apatinib, anlotinib, regorafenib, bevacizumab, sorafenib, or sunitinib), history of prior heart disease, pharmacohistory of cardiovascular drugs, smoking and drinking history, and effect of chemotherapeutic drugs on cardiotoxicity. Additionally, routine complete blood counts and coagulograms (including the AST, LDH, CK and CK-MB activities) were carried out before and after first 1 cycle of therapy. The first effective evaluation was proceeded after 21 days of treatment. All the examining were detected in the laboratory department, Guang'anmen hospital, China Academy of Chinese Medical Sciences, by using full-automatic chemistry analyzer (AU5800 series, Beckman Coulter).

### Statistical Analysis

Statistical analyses were performed using GraphPad Prism8 (GraphPad Software, San Diego, CA, USA) and SPSS statistical software version 24.0 (SPSS Inc., Chicago, IL, USA). Serum AST, LDH, CK and CK-MB activities after first one cycle of treatment were compared to that with no treatment were analyzed. Considering the predictor variables, such as age, gender, histological diagnosis, and the choice of anti-angiogenic drugs, history of prior heart disease, pharmacohistory of cardiovascular drugs, smoking and drinking history, and effect of chemotherapeutic drugs on cardiotoxicity, the statistics were done by mixed linear modeling. All data were non-normally distributed, that reported by the median, interquartile range, and min-max. The differences between tumor patient group and matched healthy control group were compared with Mann-Whitney U test. A two-sided  $P < 0.05$  was deemed as statistically significant.

## RESULTS

### Patient Characteristics

A total of 81 patients were treated by anti-angiogenic drugs during the study period. **Table 1** presents the detailed patient characteristics. There were 41 (50.6%, 95% CI: 0.397 ~ 0.615) males and 40 (49.4%, 95% CI: 0.385 ~ 0.603) females in the total cohort, with a median age of 63 years (Quartiles 25–75%, 56–70). Among the patients, there were 42.0% (34/81, 0.312 ~ 0.527) have prior heart disease history, 35.8% (29/81, 0.254 ~ 0.462) have cardiovascular drugs use history. Meanwhile, a total of 34.6% (28/81, 0.242 ~ 0.449) have smoking history and 23.4% (19/81, 0.142 ~ 0.327) have drinking history. All the patients have been treated with different chemotherapy, nevertheless,

Sorafenib	6	7.4	0.017 ~ 0.131	
Sunitinib	1	1.2	−0.012 ~ 0.036	

there were 3/81 patients were affected by chemotherapeutic drugs on cardiotoxicity.

A total of 28.4% (23/81, 95% CI: 0.186 ~ 0.382) patients had lung cancer, 16.1% (13/81, 95% CI: 0.081 ~ 0.240) had gastric cancer, 18.5% (15/81, 95% CI: 0.101 ~ 0.270) had colorectal

cancer, 6.2% (5/81, 95% CI: 0.009 ~ 0.114) had ovarian cancer, and 6.2% (5/81, 95% CI: 0.009 ~ 0.114) had liver cancer. A small number of renal cancer (4.9%, 4/81), metrocarcinoma (3.7%, 3/81), esophagus cancer (2.5%, 2/81), pancreatic cancer (2.5%, 2/81), urethral carcinoma (2.5%, 2/81), osteocarcinoma (2.5%, 2/81), breast cancer (1.2%, 1/81), cholangiocarcinoma (1.2%, 1/81), thyroid cancer (1.2%, 1/81), duodenal cancer (1.2%, 1/81), and thymoma (1.2%, 1/81) cases were included too. Except one patient is III gastric cancer, all other cancer patients were at staged IV depending on the TNM (Tumor, lymph Node, distant Metastasis). In addition, 27 of 81 patients (33.3%, 95% CI: 0.231 ~ 0.436) were treated with apatinib, 25 of 81 patients (30.9%, 95% CI: 0.208 ~ 0.409) were treated with anlotinib, 12 of 81 patients (14.8%, 95% CI: 0.071 ~ 0.226) were treated with regorafenib, 10 of 81 patients (12.3%, 95% CI: 0.052 ~ 0.195) were treated with bevacizumab, six patients were treated with sorafenib, and one patient (12.3%) were treated with sunitinib (Table 1).

## Evaluation of Serum AST and LDH Activities in Patients and Health Control

Table 2 displays the detailed characteristics of serum AST, LDH, CK, and CK-MB activities in patients and health control. Health control was matched in serum AST, LDH. Serum AST and LDH were markedly increased in patients after treatment compared with health control ( $p < 0.01$ ,  $p < 0.001$ ). In addition, it was significantly increased in patients before treatment compared with health control in serum LDH ( $p < 0.001$ ), (Figure 1).

## The Effects of Predictor Variables on Serum AST, LDH, CK, and CK-MB Activities in Patients

Afterwards, considering the predictor variables, such as age, gender, histological diagnosis, and the choice of anti-angiogenic drugs, history of prior heart disease, pharmacohistory of cardiovascular drugs, smoking and drinking history, and effect of chemotherapeutic drugs on cardiotoxicity, the statistics were done by mixed linear modeling. As Tables 3–6 showed, the influence of age, gender, cancer type, the choice of anti-angiogenic drugs, drinking history, and effect of chemotherapeutic drugs on cardiotoxicity were eliminated in this study.

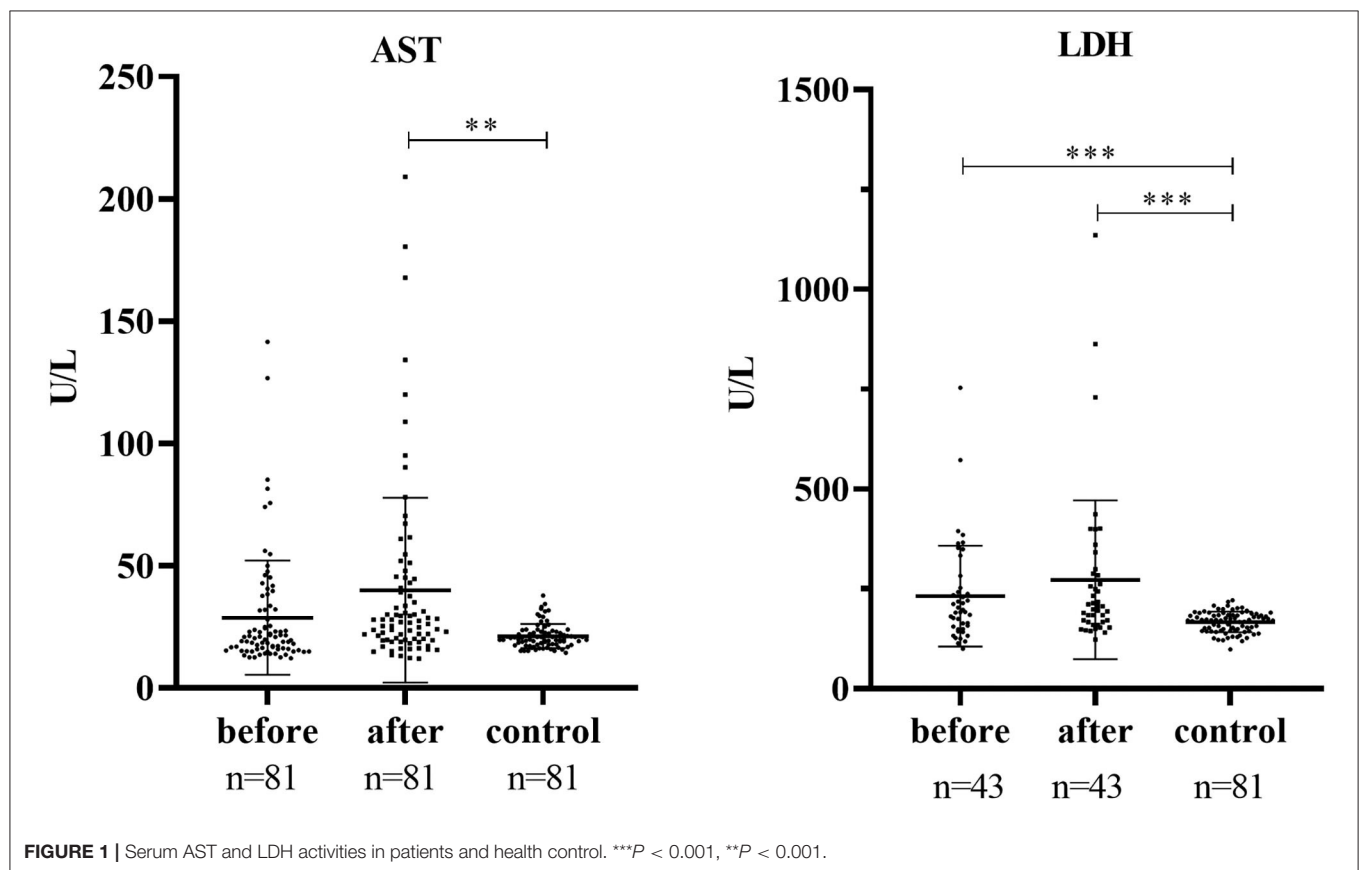

Exclude the influence of the above factors, the median of AST activities were 18.40 (10.20, 12.10–126.70) before treatment and 26.70 (24.00, 12.00–209.10) after anti-angiogenic treatment, which was markedly decreased ( $P = 0.002$ ). The mean AST activities were 11.26 higher after anti-angiogenic treatment than before, Tables 2, 7. The median of LDH activities were 192.00 (103.00, 100.00–753.00) before treatment and 206 (122.00, 123.00–1,135.00) after anti-angiogenic treatment, which was significantly decreased ( $P = 0.022$ ). The mean LDH activities were 38.58 higher after anti-angiogenic treatment than before, Tables 2, 7.

Interestingly, serum CK and CK-MB activities have been affected by anti-angiogenic treatment, history of prior heart disease, pharmacohistory of cardiovascular drugs, and smoking history. The mean serum CK activities was 14.35, significantly

**TABLE 2 |** The detailed characteristics of serum AST, LDH, CK and CK-MB activities in patients and health control.

	Group	Number	Median	Interquartile range	Min	Max
AST	Before treatment	81	18.40	10.20	12.10	126.70
	After treatment	81	26.70	24.00	12.00	209.10
	Health control	81	19.90	6.20	14.30	37.80
LDH	Before treatment	43	192.00	103.00	100.00	753.00
	After treatment	43	206.00	122.00	123.00	1,135.00
	Health control	81	176.00	98.00	119.00	217.00
CK	Before treatment	43	32.00	31.00	12.00	144.00
	After treatment	43	42.00	40.00	10.00	244.00
CK-MB	Before treatment	47	9.00	217.52	0.48	218.00
	After treatment	47	13.00	20.00	0.35	252.00

In our laboratory, 90–50 U/L is adopted as the cut-off value for normal AST; <247 U/L is adopted as the cut-off value for normal LDH; < 171 U/L is adopted as the cut-off value for normal CK; < 25 U/L is used as the cut-off value for normal CK-MB.

increased after anti-angiogenic treatment than before ( $P = 0.032$ ). Patients who had cardiovascular drugs history had 84.48 lower serum CK activities ( $P = 0.028$ ) than those without cardiovascular drugs history. Smoking history is another predictor variables, patients who had smoking history was 47.38 higher than those without ( $P = 0.042$ ), **Table 7**. Serum CK-MB activities were mainly history of prior heart disease and cardiovascular drugs. Patients who had prior heart disease history was 129.04 higher serum CK-MB activities ( $P = 0.005$ ) than those without prior heart disease history. Conversely, Patients

who had cardiovascular drugs history was 149.10 lower serum CK-MB activities ( $P = 0.002$ ) than those without cardiovascular drugs history.

## DISCUSSION

This retrospective study revealed the blood biomarkers, such as AST, LDH and CK were markedly increased with use of anti-angiogenic drugs, indicating that use of anti-angiogenic

cardiomyocytes have inflammation (myocarditis) or necrosis (myocardial infarction) due to various reasons, the enzymes contained in the cardiomyocytes can enter the blood, and the activity (content) of these enzymes in the blood increases. Elevation of these serum markers in this study did not exceed the normal upper limit, but it may indicate a tendency for long-term use to accumulate toxicity.

AST is one of the most important aminotransferases in the body. It is mainly found in tissue cells such as myocardium, liver, skeletal muscle, kidney, pancreas, spleen, lung, red blood cells, as well as in normal human plasma, bile, cerebrospinal fluid, and saliva. Medium, but it cannot be detected in urine without kidney damage. The content of AST in the myocardium is the most abundant, so it has certain significance for the diagnosis of myocardial infarction. When acute myocardial infarction (AMI) occurs, the serum AST activity generally rises to 4–5 times the upper limit of the reference value. If it reaches 10–15 times the upper limit of the reference value, it is often fatal infarction occurred. However, the rise of AST is later than CK in AMI, and recovers earlier than LDH, diagnostic value of AST for AMI is becoming less and less. Nevertheless, AST is an indispensable evaluation index in the clinical research of oncology drug evaluation. The study determined the safety and effectiveness of anti-angiogenic therapy with sorafenib and bevacizumab in patients with advanced HCC and results found that dose-limiting toxicities included hypertension, AST increase, creatinine increase, etc. (9). Patients receive intravenous ramucirumab (8 mg/kg) every 2 weeks were observed in a phase 3 clinical trial. Hypertension (34 [12%] of 277 patients treated with ramucirumab), increased AST concentration (15 [5%]), thrombocytopenia (13 [5%]), etc. were occurred with grade 3 or greater adverse events (10). LDH is an extremely important enzyme that regulates the conversion of pyruvate to lactic acid in anaerobic glycolysis and play an important role in cancer metabolism (11). Meanwhile, LDH is a useful marker for predicting the efficacy of bevacizumab-containing chemotherapy in patients with metastatic colorectal cancer (12). It is widely present in the cytoplasm and mitochondria of tissue cells such as liver, heart, skeletal muscle, lung, spleen, brain, red blood

cells, platelets, etc. LDH is a tetramer composed of two different subunits (LDHA and LDHB), forming 5 isoenzymes with M-type and H-type subunits: H4(LD1), MH3(LD2), M2H(LD3), M3H(LD4), M4(LD5). Different tissues have their characteristic isoenzymes. The ratios of LD isoenzymes in the heart, kidney and red blood cells are similar, with LD1 and LD2 dominating. When the myocardium is damaged, the myocardial cell membrane ruptures, and the mitochondria and cytoplasmic substances leak out into the intercellular fluid and peripheral blood. In response to the hypoxic characteristic of the tumor microenvironment, cancer cells generate a large amount of lactate *via* the metabolism of glucose and glutamine (13, 14). High levels of LDHA expression serves as a prognostic indicator in patients with different type of cancers (15). LDH increased production of reactive oxygen species and regulate cell apoptosis and autophagy (16). Thus, the role of LDH in tumor biology is more complex and may as a potential target in the treatment of cancer. Although in this study, the elevation of AST and LDH in patients did not exceed the normal upper limit, there was a significant increase in serum AST and LDH activities, compared with the matched healthy control.

But it is regrettable that the serum CK and CK-MB activities of matched healthy control were not found. All healthy control were from a medical examination at our hospital, serum CK and CK-MB activities are not included in the physical examination at present. Interestingly, serum CK and CK-MB activities have been affected by history of prior heart disease, cardiovascular drugs, and smoking.

CK mainly exists in skeletal muscle and cardiac muscle, and brain tissue. CK is an important energy regulating enzyme in the myocardium. Under the energy provided by ATP, it catalyzes the reversible phosphorylation of ATP and creatine to ADP and phosphocreatine in cellular energy metabolism, which can be transported to the cytoplasm and stored. Serum CK can be increased in various types of progressive muscle atrophy. CK begins to increase 2–4 h after AMI and can reach 10–12 times

the upper limit of normal. It has higher specificity than AST and LDH for diagnosing myocardial infarction, but the increase of this enzyme lasts for a short time, and it returns to normal after 2–4 days. There are three isoenzyme formations for CK: CK-MB (mostly in the heart), CK-MM (mostly in the muscle), or CK-BB (mostly in the brain) (17). CK-MB activity has been recognized as a specific and sensitive biomarker of clinical and subclinical myocardial injury (8, 18). CK-MB activities are significantly positively correlated with the extent of myocardial injury, so serum CK-MB can be used as a biomarker for AMI (19). The presence of CK-MB in patients with cancers may cause confusion with AMI. Serial determinations of both CK and LDH are of great help in differential diagnosis 3512170. In addition, a previous study demonstrated that an elevated serum CK-MB in cancer patients may be associated with cardiac insufficiency, severe illness status, and have high mortality (20). Even a slight increase in CK-MB indicated the possibility of myocardial infarction (21). There has been no retrospective report focusing on CK, CK-MB and anti-angiogenic therapy. In the present study, both CK and CK-MB levels were significant elevated after use anti-angiogenic drug. Myocardial ischaemia might be the reason for the slight increase in CK and CK-MB. Furthermore, Some studies have demonstrated that CK-MB-to-total-CK ratio could be clinically utilized as a primary screening tool for cancer (22), which is an easily available indicator. In this study, we found that patients who had prior heart disease history had a higher serum CK-MB activities, while in patients who had cardiovascular drugs history had a lower serum CK and CK-MB activities on the contrary. The reason for the result is likely to be that people with previous cardiovascular disease have damage to heart muscle cells, while the drugs reduce the damage, which need to be further studied.

## CONCLUSIONS

Our findings suggest that the serum AST, LDH and CK activities of patients who had used anti-angiogenic drugs were likely

to have elevated. History of prior heart disease, cardiovascular drugs, and smoking should be considered in the anti-angiogenic treatment. AST, LDH, CK and CK-MB are indicators of myocardial muscle injury, such as myocarditis or myocardial infarction. Use of anti-angiogenic drugs should not be assumed to be completely safe and without any cardiovascular risks. In addition, attention should also be paid to long-term use to accumulate toxicity. Apparently, the number of cases in patients should be expanded and more detailed research should be done in the future.

**Introduction:** Ibrutinib, a Bruton's tyrosine kinase inhibitor (TKI) used primarily in the treatment of hematologic malignancies, has been associated with increased incidence of atrial fibrillation (AF), with limited data on its association with other tachyarrhythmias. There are limited reports that comprehensively analyze atrial and ventricular arrhythmia (VA) burden in patients on ibrutinib. We hypothesized that long-term event monitors could reveal a high burden of atrial and VAs in patients on ibrutinib.

**Methods:** A retrospective data analysis at a single center using electronic medical records database search tools and individual chart review was conducted to identify consecutive patients who had event monitors while on ibrutinib therapy.

**Results:** Seventy-two patients were included in the analysis with a mean age of  $76.9 \pm 9.9$  years and 13 patients (18%) had a diagnosis of AF prior to the ibrutinib therapy. During ibrutinib therapy, most common arrhythmias documented were non-AF supraventricular tachycardia ( $n = 32$ , 44.4%), AF ( $n = 32$ , 44%), and non-sustained ventricular tachycardia ( $n = 31$ , 43%). Thirteen (18%) patients had  $>1\%$  premature atrial contraction burden; 16 (22.2%) patients had  $>1\%$  premature ventricular contraction burden. In 25% of the patients, ibrutinib was held because of arrhythmias. Overall 8.3% of patients were started on antiarrhythmic drugs during ibrutinib therapy to manage these arrhythmias.

**Conclusions:** In this large dataset of ambulatory cardiac monitors on patients treated with ibrutinib, we report a high prevalence of atrial and VAs, with a high incidence of treatment interruption secondary to arrhythmias and related symptoms. Further research is warranted to optimize strategies to diagnose, monitor, and manage ibrutinib-related arrhythmias.

**Keywords:** cardio-oncology, tyrosine kinase inhibitor, atrial fibrillation, ventricular arrhythmia, ibrutinib, ambulatory event monitor

## INTRODUCTION

Atrial fibrillation (AF) is the most common sustained arrhythmia in the world, affecting at least 33 million individuals. The burden of AF has been rapidly increasing worldwide due to growing awareness and the broader application of portable event monitors and wearables and also due to shifts in demographics and an increase in the prevalence of risk factors (1). Moreover, with the

growing use of cancer therapies in clinic, antineoplastic agents such as paclitaxel, mitoxantrone, doxorubicin, and TKIs have been associated with an increased risk of developing AF (2–5).

Ibrutinib is a Bruton's TKI that is used in a growing number of hematologic malignancies. It irreversibly binds Bruton's tyrosine kinase, which plays a critical role in B-cell development and proliferation, and thereby exerts its anticancer activity primarily in B-cell malignancies including chronic lymphocytic leukemia, mantle cell lymphoma, and Waldenström's macroglobulinemia (6). The use of ibrutinib has been associated with increased incidence of AF (5); with limited data on its association with other arrhythmias. These arrhythmias lead to a relatively high treatment interruption rate and cause significant morbidity in this patient population (4). There are limited data to date that comprehensively analyze both atrial and ventricular arrhythmia (VA) burden in patients on ibrutinib, and subsequent referral to subspecialty care, antiarrhythmic drug use, and treatment interruption patterns. Therefore, we hypothesized that long-term event monitors, as defined by continuous ECG monitoring >48 h, could reveal a high burden of atrial and VAs in patients on ibrutinib therapy which may lead to treatment cessation.

## METHODS

We performed a single-center, retrospective cohort study to analyze consecutive patients on ibrutinib therapy, who had event monitors of at least 3 days of duration for any indication while on ibrutinib therapy between the years 2014 and 2021.

### Data Source and Covariates

Patient data including demographics, past medical history, history of AF, echocardiographic data (including left ventricular ejection fraction (LVEF), left atrial volume index (LAVI), and left atrial diameter), 12-lead ECGs, and event monitors with autotriggers were collected from electronic medical records. Event monitors were manually reviewed to confirm the diagnosis of AF, patterns of other arrhythmias seen, and assess the types of ventricular tachycardia (monomorphic vs. polymorphic). CHA<sub>2</sub>DS<sub>2</sub>-VASc score was automatically calculated from these data using age, sex, history of heart failure, hypertension, stroke, TIA, vascular disease, and diabetes.

### Outcomes

We compared the cohort that had AF seen on the event monitor against the cohort that did not, and the cohort that had ibrutinib held vs. those in whom ibrutinib was continued. We also conducted univariate analyses to identify the correlation between the development of AF and any clinical risk factors including ECG and echocardiographic parameters, and also a correlation between ibrutinib being held and any clinical risk factors.

### Statistics

Statistical analyses were done using SPSS version 27 (IBM SPSS Statistics for Mac, IBM Corporation, Armonk, NY). Continuous data are reported as mean  $\pm$  standard deviation, unless otherwise stated, and are tested for normality using the Shapiro–Wilk test ( $p > 0.05$ ). Independent-samples  $t$ -test and Mann–Whitney U

test were run to determine whether there were differences in mean values between cohorts and for analysis of continuous data. Categorical variables were compared using the Pearson's chi-squared test or Fisher's exact test where expected frequencies were <5. Statistical significance was assumed at the 5% level. This study was approved by the Institutional Review Board of Stanford University.

## RESULTS

### Clinical Characteristics

Of 755 patients who were on ibrutinib therapy for hematologic malignancies at Stanford Hospital between 2014 and 2019, 72 patients had event monitors (Zio, iRhythm Technologies, Inc., CA) while on ibrutinib therapy and were included in this analysis (Table 1). Thirteen patients (18%) carried a diagnosis of AF prior to ibrutinib therapy but the majority of the patients did not have a screening Holter monitoring, and therefore, the burden of pre-ibrutinib therapy arrhythmia is unknown. The most common indications for event monitoring included atrial arrhythmias (50%), palpitations (23%), abnormal EKG (14%), and syncope (6%). The 72 patients who were included in the analysis had a mean age of  $76.9 \pm 9.9$  years, 25% were women, 68% with a diagnosis of hypertension, 62% with hyperlipidemia, 13% with COPD, 10% with prior history of cardiac surgery, mean BMI of  $24.8 \pm 4.1$ , and mean CHA<sub>2</sub>DS<sub>2</sub>-VASc score of  $4 \pm 2$  (Figure 1A). The mean LVEF was  $58.1 \pm 9.1\%$  and the mean LAVI was  $36.4 \pm 13.0$  (ml/m<sup>2</sup>). Thirteen (18%) patients had a history of AF prior to initiation of ibrutinib. The average duration of time on ibrutinib therapy for all patients with event monitors was  $31.9 \pm 22.3$  months. The median number of months on ibrutinib therapy was 28 months (range 1–111 months).

### Arrhythmia Patterns on Long-Term Event Monitors

Most common arrhythmias documented were non-AF supraventricular tachycardia (SVT, in  $n = 32$ , 44.4% of patients), AF ( $n = 32$ , 44.4%), and non-sustained ventricular tachycardia (NSVT  $n = 31$ , 43.1%). Fourteen (19.4%) patients had >1% premature atrial contraction (PAC) burden; 16 (22.2%) patients had >1% premature ventricular contraction (PVC) burden (Figure 1B). Out of patients that had NSVT, five patients had polymorphic NSVT whereas the rest had monomorphic NSVT. Median QTc in patients with NSVT was 422 ms (range 375–507). Sixteen (22.2%) patients had both NSVT and AF recorded, which is about half of the population which had either NSVT or AF (Figure 2). A small proportion of these patients were followed by electrophysiologists ( $n = 20$ , 27.8%), whereas a higher proportion were followed by cardiologists ( $n = 50$ , 69.4%).

### Factors Associated With Ibrutinib Therapy Interruption

In 18 (25%) patients, ibrutinib therapy was held because of arrhythmias and/or related symptoms (Table 2). Six (8.3%) patients were started on antiarrhythmic drugs during ibrutinib

therapy to manage these arrhythmias. Three patients required at least one direct current cardioversion (DCCV) for poorly controlled AF. Interruptions in ibrutinib therapy were associated with >1% PAC burden on event monitor while on ibrutinib therapy ( $p = 0.002$ ) and a prior history of VT ( $p = 0.017$ ); but not with the presence of the PVC burden of >1%, SVT, AF, or NSVT (all,  $p > 0.05$ ) on the event monitor. Neither history of prior AF nor gender correlated with the frequency at which Ibrutinib was held. Patients in whom ibrutinib was held for arrhythmias were more likely to be seen by a cardiac specialist ( $p = 0.005$ ), along with patients on ibrutinib whose Holter monitors showed NSVT ( $p < 0.001$ ). Female patients were referred to a cardiac specialist less frequently than their male counterparts ( $p = 0.14$ ).

When looking at transthoracic echocardiography data, patients in whom ibrutinib was held for arrhythmia had a lower LVEF vs. those in whom ibrutinib was not held, albeit

not statistically significant ( $55.1 \pm 10.7$  vs.  $59.3 \pm 8.2\%$ ;  $p = 0.09$ ). However, for patients who had an LVEF  $\leq 50\%$ , 5 out of 12 (41.7%) had ibrutinib held for arrhythmias, which is considerably higher than the entire cohort (25%). Patients with a larger LA volume index had a higher probability of having ibrutinib held for arrhythmias (LAVI  $43.3 \pm 15.9$  vs.  $33.6 \pm 10.7$  ml/m<sup>2</sup>;  $p = 0.007$ ). For those who were detected to have AF on event monitors ( $n = 32$ , 44%), EF was slightly lower ( $55.8 \pm 8.9\%$  vs.  $60.0 \pm 8.9\%$ ;  $p = 0.059$ ), although it did not reach statistical significance.

There was no statistically significant relationship between AF on event monitor and risk factors such as age, hypertension, EKG, and echocardiographic parameters. No statistically significant difference was found between the cohort that developed AF and the cohort that did not. There was no statistically significant relationship between prior AF history and LA size or EF.

## DISCUSSION

In this large dataset of long-term event monitors on patients treated with ibrutinib, we conduct detailed characterization of their arrhythmias which demonstrate a high burden of both atrial and VAs, with a high incidence of treatment interruption secondary to arrhythmias and a low rate of referral to specialists for arrhythmia management.

The incidence of atrial arrhythmias during ibrutinib therapy is well documented, ranging from 8 (7) to 14% (8) in prospective studies, and up to 40% in patients referred to cardio-oncology clinics (9). Compared with other TKIs, ibrutinib therapy has been the most consistent and independent risk factor associated with subsequent AF. These are several-fold higher than the

reported incidence of both AF and NSVT on patients with non-cancer who received event monitors (10, 11). Despite the high incidence of AF in this population, it remains unknown which patients are at a higher risk for developing AF. While limited studies suggest advanced age, valvular disease, and prior history of AF to increase this risk (12, 13), these risk factors were not consistently found significant. Moreover, in this study, we did not find significant correlation with any clinical or demographic factors in patients who developed AF, which may be due in part to the limited sample size. We also did not find any significant correlation between the duration of the ibrutinib therapies and the development of AF. To better identify risk factors or predictors of ibrutinib-related AF, a more comprehensive large cohort study would be warranted.

In this study, ibrutinib therapy was held in 18 (25%) patients because of arrhythmias and/or related symptoms. We identified factors such as >1% PAC burden on event monitor while on ibrutinib therapy, a prior history of VT ( $p = 0.017$ ), a high LA volume index, and low LVEF to be significantly associated with increased likelihood of ibrutinib therapy interruption due to arrhythmia or related symptoms. We believe a high LA volume index which correlates with high LA pressure and/or low LVEF may be significant as they can predispose the myocardium to develop subsequent arrhythmia. Otherwise, we were unable to obtain reliable data regarding rates of ibrutinib being held in the cohort that did not have event monitors. According to limited study reports available, rates of ibrutinib discontinuation are as high as 35% and AF seems to be the most common reason for ibrutinib being held in a comparable population of patients with hematologic malignancies (14, 15).

Data regarding VA during ibrutinib or other TKI therapies are rather scant. Some studies have used large registries of patients with cancer and looked at adverse events of VAs while on ibrutinib therapy. They found that even after

**TABLE 2 |** Detailed personalized information about patients in whom ibrutinib therapy was held.

Patients in whom ibrutinib was held	Reason for ibrutinib interruption	Time on ibrutinib (months)	History of arrhythmia (AF or VT) prior to ibrutinib initiation	EF (%)	NSVT on Zio	QTc (ms)	Re-challenge

Patient 18	Recurrent AF	4	AF	41	No	N/A	No

accounting for baseline CV risk factors, ibrutinib was associated with a much higher incidence of VAs compared to similar patients not taking ibrutinib with a risk ratio up to 12.4 (16). When estimating the incidence of VAs in clinical trials involving ibrutinib, it was found that the incidence of VAs was significantly higher in patients receiving ibrutinib therapy compared to non-ibrutinib therapies (17). Yet, the detailed characterization, subtypes, and true incidence of VAs remain unknown as only symptomatic, clinical events were included in the analysis.

This study is unique in that it utilizes Holter event monitors which record all arrhythmic events, inclusive of both symptomatic and asymptomatic, over 2 weeks to comprehensively and unbiasedly characterize VAs among the patients treated with ibrutinib. In this study, the incidence of VAs was substantially higher with NSVTs captured in 43% of patients and a >1% burden of PVCs in up to 22% of symptomatic or arrhythmia-prone patients who were treated with ibrutinib and required Holter monitor screening. The observed rate of NSVT is an order of magnitude higher than the reported incidence of NSVT without known heart disease, which is generally in the range of 0.5–1% (18). Our results support the notion that ibrutinib is associated with a more frequent occurrence of VAs than previously believed. This finding also raises the question of underdiagnosis of VAs in patients treated with ibrutinib and emphasizes the need for further research in and more intensive

monitoring of arrhythmias associated with ibrutinib therapy, and also other TKIs.

Multiple mechanisms have been proposed regarding the pathogenesis of TKI-induced arrhythmia. A recent study showed that off-target inhibition of C-terminal Src kinase (CSK), a non-receptor tyrosine kinase that inhibits Src kinase family members, may be responsible for the increased arrhythmogenicity seen with ibrutinib therapy (19). While CSK was reported to be expressed at a lower level in bulk ventricular vs. atrial tissue (19), it was found in both atrial and ventricular myocytes to a similar level (20) at the individual cell level which might explain the high burden of VAs observed in our study. Other proposed mechanisms for VAs due to ibrutinib include QTc prolongation and enhanced automaticity. In our cohort, the QTc of patients who developed NSVT was not found significantly prolonged (median duration of 422 ms).

Limitations of our study include patients enrolled in a single center, relatively small size of patients, and the absence of event monitors in all patients on ibrutinib. Notably, patients included in our study had an event monitor placed due to symptoms, ranging from palpitations to syncope, which can induce a selection bias to overestimate the incidence of arrhythmias in this patient population. Our cohort also consisted of older patients with a mean age of 77 years, more male patients, and patients with a modest burden of cardiovascular risk factors, all of which are known risk factors for developing

atrial or VA. No statistically significant correlation was found between development of AF and clinical risk factors which have been shown to be related in larger studies such as age and hypertension, likely due to the small sample size of our cohort. Given the limited size of the cohort, only descriptive and univariate statistical analyses were performed. Additional clinical data such as alcohol intake data and prescription of other AF-inducing drugs could not be reliably obtained from our retrospective chart review and therefore not included in this analysis. Regarding non-AF SVT, we were unable to further classify the subtypes due to the limited quality of signals. Finally, we were unable to get the rates of ibrutinib discontinuation from the cohort that did not have event monitors placed to compare them to the patients included in this analysis. As such, a prospective and multicenter study would be warranted to better characterize arrhythmia associated with ibrutinib therapy.

## CONCLUSION

In this large dataset of Holter monitors on patients treated with ibrutinib, we find a significant burden of both atrial and VAs resulting in treatment interruption due to arrhythmias and related symptoms. Our results highlight the need for intentional monitoring and management of both atrial and VAs when patients are treated with ibrutinib therapy.

In recent years, the incidence of breast cancer has been increasing on an annual basis. Human epidermal growth factor receptor-2 (HER-2) is overexpressed in 15-20% human breast cancers, which is associated with poor prognosis and a high recurrence rate. Trastuzumab is the first humanized monoclonal antibody against HER-2. The most significant adverse effect of trastuzumab is cardiotoxicity, which has become an important factor in limiting the safe use of the drug. Unfortunately, the mechanism causing this cardiotoxicity is still not completely understood, and the use of preventive interventions remains controversial. This article focuses on trastuzumab-induced cardiotoxicity, reviewing the clinical application, potential cardiotoxicity, mechanism and discussing the potential interventions through summarizing related researches over the past tens of years.

**Keywords:** trastuzumab, cardiotoxicity, breast cancer, adverse reaction, rational drug use

## INTRODUCTION

Currently, the incidence of breast cancer has been increasing year by year, and now has the greatest incidence of malignant tumors worldwide, with obvious geographical differences. According to GLOBOCAN 2020 estimates of cancer incidence and mortality produced by the International Agency for Research on Cancer, female breast cancer has surpassed lung cancer as the most commonly diagnosed cancer, with an estimated 2.3 million new cases (1). Human epidermal growth factor receptor-2 (HER-2) is an important biomarker for breast cancer as well as a therapeutic target. Of breast cancer patients, 15-20% are HER-2 positive, which is usually considered the most serious subtype due to its poor prognosis and high recurrence rate (2, 3). Trastuzumab is a humanized monoclonal antibody directed against HER-2, initially approved as first-line treatment of HER-2-positive recurrent metastatic breast cancer in 1998. Introduction of trastuzumab to chemotherapeutic regimes has significantly increasing the life expectancy of patients with HER-2 positive, aggressive breast cancer. Meanwhile, there have been increasing reports of trastuzumab-induced cardiotoxicity (TIC) in recent years. To date, the most

relevant clinical solution for TIC is trastuzumab interruption, but this approach may cause cancer recurrence. Therefore, understanding the mechanism of TIC and the related preventive measures is paramount for the safe and effective treatment of HER2-positive breast cancer patients. Here, we have attempted to provide an overview of our current knowledge of this effect, focusing primarily on clinical manifestations, influencing factors and mechanism. We also discussed the prevention and pretreatment, with the goal of providing reference for related research and clinical use.

## OVERVIEW OF TRASTUZUMAB FOR HER-2-POSITIVE BREAST CANCER

Trastuzumab is an important HER-2 targeted drug. The gene encoding HER-2 is localized on chromosome 17 (4) and encodes a transmembrane glycoprotein with tyrosine kinase activity that plays an important role in cell survival, proliferation, and differentiation (5, 6). HER-2 is a member of the epidermal growth factor receptor (EGFR) family and has two forms of activation, homodimerization and heterodimerization with other receptors in the family (HER-1, HER-3, HER-4), either of which triggers cellular pathways including MEK/Erk, PI3K/Akt (7, 8). The mechanism of trastuzumab has not been fully elucidated and may be related to inhibiting the formation of the homodimer by binding to the HER2 extracellular structural domain IV, blocking downstream cellular pathways and thus blocking tumor cell proliferation (9, 10). Recently, Tsao et al. (11) found that the dominant therapeutic mechanism of trastuzumab is through its elicitation of tumor associated macrophages, which mediated antibody-dependent cellular phagocytosis. After HER2 overexpression was discovered to be associated to poor clinical outcomes in breast cancer patients, it quickly became the focus of intensive investigations. In 1989, Hudziak et al. (12) found that a mouse monoclonal antibody to HER-2 successfully inhibited the proliferation of breast cancer cells. Researchers humanized mouse-derived 4D5 monoclonal antibodies and the most active of these was named trastuzumab (13). It was approved by the FDA in 1998 for first-line treatment of HER-2-positive recurrent metastatic breast cancer. Trastuzumab in combination with other agents significantly prolonged median survival (25.1 vs. 20.3 months;  $p < 0.008$ ), progression-free survival (7.4 vs. 4.6 months;  $p < 0.001$ ), improved objective remission rates (50 vs. 32%;  $p < 0.001$ ), and reduced one-year mortality (22 vs. 33%;  $p < 0.008$ ) (14). Several large foreign clinical trials have shown that the use of trastuzumab after receiving chemotherapy can significantly reduce the risk of breast cancer recurrence and death (15–17). Furthermore, a joint analysis of two large clinical trials (NCCTG N9831 and NSABP B-31) found that patients with early-stage HER2-positive breast cancer benefited from the addition of trastuzumab to conventional chemotherapy followed by treatment with paclitaxel, resulting in a significant and sustained reduction in cancer recurrence rates and a 37% improvement in overall survival (18). Both *Chinese guidelines for diagnosis and treatment of pancreatic cancer 2019* and *NCCN Clinical Practice Guidelines in Oncology* recommend trastuzumab

as the first choice in combination with chemotherapy drugs (19).

## CLINICAL MANIFESTATIONS OF TRASTUZUMAB-INDUCED CARDIOTOXICITY

It is generally accepted that, unlike anthracyclines, the cardiotoxicity caused by trastuzumab is not dose-dependent, does not occur in all patients, and is reversible (20). Left ventricular dysfunction (LVD) and heart failure (HF) are relatively common and severe manifestations of cardiotoxicity in cancer therapy (21). The Cardiac Review and Evaluation Committee (CREC) defined the cardiotoxicity as one of the following: (1) cardiomyopathy characterized by a decrease in cardiac left ventricular ejection fraction (LVEF) that was either global or more severe in the septum; (2) symptoms of congestive heart failure (CHF); (3) associated signs of CHF, including but not limited to S3 gallop, tachycardia or both; and (4) decline in LVEF of at least 5 to  $<55\%$  with accompanying signs or symptoms of CHF or a decline in LVEF of at least 10% to  $<55\%$  without accompanying signs or symptoms (22). Any of the above can be defined as cardiotoxicity. A frequently used definition of treatment-related cardiotoxicity in clinical trials is an absolute decrease in LVEF of 10% to a value of  $<55\%$  (23). Of these definitions, there may be differences between individual patients regarding the decrease in LVEF. Researchers analyzed 1,437 echocardiograms from 324 patients over a follow-up period of up to 3.5 years, and revealed three main patterns of LVEF change over time: (1) steady decline over time; (2) mild early and late sustained decline; (3) early significant decline with late partial recovery (24).

In addition to left ventricular dysfunction and heart failure, studies also reported the development of arrhythmias, sick sinus node syndrome, and atrial flutter in patients undergoing treatment with trastuzumab (25). Recently, through a secondary analysis of a clinical trial, investigators found that TIC is characterized by the presence of both left ventricular dysfunction and reversible myocardial inflammation and edema, and that trastuzumab may be associated with deleterious changes in cardiac metabolic phenotype (26).

## THE INCIDENCE AND INFLUENCING FACTORS OF TIC

Many clinical studies have demonstrated the cardiotoxicity associated with trastuzumab, and this article focuses on a few large clinical studies of adjuvant therapy with combination or sequential trastuzumab. In the N9831 study (27), in the two trial groups using trastuzumab, the cumulative incidence of CHF or cardiac death over 6 years was 2.8 and 3.4%, respectively, resulting in risks that were 4.7 and 5.7 times higher than not using trastuzumab. The BCIRG006 (17) study found that the addition of trastuzumab after anthracycline treatment significantly increased the odds of CHF, and the risk of decreased LVEF was 1.6 times greater than without trastuzumab.

Furthermore, the incidence of cardiac events reported by NSABP B-31 were 1.3% in the control group and 4.0% in the trastuzumab group, with 15.5% of the trastuzumab group discontinuing the drug for cardiac reasons (28). The BIG1-01 (HERA) study (16, 29) conducted a comparative trial of 5102 HER-2 positive early-stage breast cancer patients over 1 and 2 years, respectively. Although the incidence of severe CHF was 0.8% in both groups, the incidence of asymptomatic drop in LVEF was significantly higher in patients on trastuzumab for 2 years (7.2%) than for 1 year (4.1%). The rate of discontinuation of treatment due to TIC was 5.2% during the 1-year period and 9.4% during the 2-year period. Additionally, an 11-year follow-up of the study found that the most of the TIC occurred during the patients' dosing period and no delayed cardiotoxicity was seen (See **Table 1**).

The incidence varies depending on the assay and criteria for cardiotoxicity used by researchers amongst the different clinical trials, as well as on the selection of patients participating in the trials. For example, in the HERA trial, a lower incidence of cardiotoxicity may be due to the exclusion of patients who had a cardiac event prior to treatment from the trial. Because patients with significant disease, including those at high risk for cardiovascular disease, are often excluded from randomized controlled trials, the incidence may differ from the real world. A real-world study based on trastuzumab for cardiotoxicity due to HER2-positive breast cancer that included more than 3,700 study subjects showed a CHF incidence of 2.8%, with a 1.0% incidence of severe CHF (31).

Risk factors for development of TIC include previous anthracycline exposure and conventional cardiovascular risk factors. Several clinical studies have demonstrated that previous anthracycline exposure appears to be the most important factor in worsening cardiotoxicity (32, 33). This may be related to the fact that the inhibition of the HER2 pathway by trastuzumab exacerbates damage caused by oxidative stress induced by anthracyclines, allowing for further accumulation of ROS (34).

In addition to co-administration, conventional cardiovascular risk factors have been associated with TIC. A recently published systematic review and meta-analysis focusing on the relationship between conventional cardiac risk factors and trastuzumab-induced cardiotoxicity in breast cancer treatment showed that age  $\geq 60$  (OR 2.03, 95% CI 1.38–3.00,  $P = 0.0004$ ), hypertension (OR 2.01, 95% CI 1.30–3.09,  $P = 0.002$ ), smoking (OR 1.33, 95% CI 1.07–1.65,  $P = 0.01$ ), diabetes (OR 1.49, 95% CI 1.22–1.81,  $P = 0.0001$ ), family history of coronary artery disease (OR 5.51, 95% CI 1.76–17.25,  $P = 0.00001$ ), known history of coronary artery disease (OR 6.27, 95% CI 2.22–17.69,  $P = 0.0005$ ) were strongly associated with the development of TIC (35). Besides, combination of obesity and being overweight was also a significant influencing factor (36).

## MECHANISM OF TRASTUZUMAB-INDUCED CARDIOTOXICITY

The exact mechanism of TIC has not been fully elucidated, and numerous *in vitro* and *in vivo* studies suggest that it

may involve multiple cellular and molecular mechanisms (37). The inhibition of NRG-1/HER and downstream signaling pathways has always posed a plausible explanation for TIC, but the underlying molecular mechanisms still remain undefined. In addition, recent research has investigated the inhibition of autophagy and alterations in cellular metabolic pathways in cardiomyocytes as potential causes for the development of cardiotoxicity.

## Downregulation of HER2 Signaling and Cardiotoxicity

In addition to being expressed in tumor tissue, HER2 has been shown to be expressed in adult cardiomyocytes along with other members of the family (HER1, HER3 and HER4) (8). HER2, together with its ligand, NRG1, is closely tied to the maintenance of adult cardiac function and the development of cardiomyocytes. When the heart becomes hemodynamically unstable or stimulated, cardiac microvascular endothelial cells can release NRG1 (38, 39). After acting in a paracrine form in cardiomyocytes, NRG1 binds to HER4 and triggers HER4/HER4 homodimerization or HER4/HER2 heterodimerization, which can later trigger a series of pathways including the MAPK pathway and PI3K-Akt (40).

The activation of the Akt family can trigger many proteins through phosphorylation, thereby initiating tumor cell survival and inhibiting apoptosis (41). Ravingerova et al. (42) used a chronic cardiac ischemia rat model to discover that Akt also increases glucose and lipid metabolism in cardiomyocytes through nutrient uptake and ensures energy in cardiomyocytes during hypoxia. Furthermore, the activation of the PI3K-Akt pathway promotes nitric oxide (NO) production in adult ventricular myocytes, thereby protecting them from oxidative stress. Moreover, Akt can initiate alterations in mitochondrial respiration, thereby reducing reactive oxygen species (ROS) production and improving cell survival. If HER2 signaling is blocked, PI3K-Akt pathway blockade will cause the accumulation of ROS in cardiomyocytes, thereby triggering the apoptosis of cardiomyocytes (43).

The MAPK pathway is another pathway associated with TIC. The MAPK pathway consists mainly of three protein kinases, Raf/MEK/ERK, that cascade to amplify external signals and thus cause cell proliferation and differentiation (44). Meanwhile, the phosphorylation of ERK1/2, inhibits the opening of the mitochondrial osmotic transition pore and suppresses the decrease in membrane potential, thus stabilizing mitochondrial function (45).

In summary, the activation of NRG1/HER and downstream signaling pathways plays an important role in protecting the stability of cardiac function. Trastuzumab inhibits the dimerization of HER4/HER2 by binding to HER2 and thereby inhibiting the above pathways (see **Figure 1**), which may be one of the potential mechanisms for TIC. In fact, NRG1/HER signaling in the heart is part of a stress-activated compensatory system that plays a minor role under physiological conditions, but can play a protective role when the heart is exposed to cardiotoxic drugs or ischemia, which is consistent with the reality

**TABLE 1** | Cardiac toxicity induced by trastuzumab.

TRIAL (Ref.)	Median follow-up time	Enrolled patients	Design	Asymptomatic drop in LVEF ( $\geq 10$ -55%)	Severe CHF/CE
NCCTG(Alliance)N9831 (27)	9.2	1,944	AC-paclitaxel	20.5%	0.6%
			AC-paclitaxel-H	19.6%	2.8%
			AC-paclitaxel plus H-H	22.5%	3.4%

			6 months of AC-H	2%(CHF, or LVEF $\geq 10$ -55%)	

A, anthracyclines; C, cyclophosphamide; H, trastuzumab; CE, cardiac event.  
CHF, congestive heart failure.

**FIGURE 1** | A proposed cellular mechanism of the cardiotoxicity of trastuzumab. Trastuzumab inhibited Her2/4 dimerization, preventing autophosphorylation and subsequent downstream pathways such as PI3K/Akt and MAPK.

that trastuzumab increases cardiotoxicity when combined with anthracyclines (46, 47).

## Inhibition of Autophagy

Autophagy is a catabolic process that aims to recycle cellular components and damaged organelles in response to different stress conditions (48). Thomas et al. found that deletion of the anti-apoptotic protein MCL-1 in mouse cardiomyocytes leads

to the inhibition of autophagy, eventually resulting in heart failure, and further indicated that MCL-1 deficiency is associated with mitochondrial dysfunction (49). Mohan et al. found that trastuzumab treatment decreased the protein expression of autophagy-related signaling molecules such as ATG5-12, ATG7, ATG14, and Beclin 1, and also demonstrated that trastuzumab-mediated inhibition of autophagy resulted in increased ROS production in cardiomyocytes (50). In earlier years, some

researchers found that anthracycline increases autophagy and that this is closely related to its cardiotoxicity, which also suggests that anthracyclines and trastuzumab differ in their mechanisms of inducing cardiotoxicity (51, 52).

### Alterations of Cardiomyocyte Metabolism

The inhibition of the NRG1/HER signaling pathway still does not fully answer the question of why trastuzumab causes cardiotoxicity. For example, TIC is often reversible in clinical settings, which contradicts the above explanation that blocking the HER2 pathway leads to cardiomyocyte apoptosis. Alterations in cardiac energy metabolism are a key feature of heart failure and are thought to exacerbate its progression (53). Necela et al. (54) found that after trastuzumab treatment, there was a reduction in glucose uptake in human induced pluripotent stem cell-derived cardiomyocytes (IPSC-CMs) as well as a significant downregulation of SLC6A6. SLC6A6 is a metabolism-related gene, and SLC6A6 knockout mice exhibit a cardiomyopathy with myocardial atrophy phenotype, which also provides a potential mechanism for TIC (55). Recently, investigators have found that clinically relevant doses of trastuzumab impaired the contractile and calcium regulatory functions of IPSC-CMs but did not lead to cardiomyocyte death, and that further RNA-SEQ with subsequent functional analysis revealed that mitochondrial dysfunction and altered cardiac energy metabolic pathways were the main causes of the TIC phenotypes, thus suggesting that metabolic modulators are important for the treatment of TIC (56).

## PREVENTION AND TREATMENT OF TIC

### Monitoring of TIC

Strict monitoring of cardiotoxicity during the treatment of trastuzumab facilitates timely adjustment of dosing and optimization of treatment regimens by clinicians. LVEF, measured by cardiovascular magnetic resonance (CMR) or 2-dimensional echocardiography (2DE), is currently the most commonly used index for monitoring left ventricular function, but LVEF has limitations and often underestimates cardiac compromise in patients. In a retrospective study, investigators found that baseline left ventricular end-diastolic volume (LEVD) was an independent predictor of cardiotoxicity and more reliably identified patients at high risk of cardiotoxicity (57). Besides, echocardiographic measurement of longitudinal shortening of the heart during contraction, or global longitudinal strain (GLS), can identify early changes in left ventricular contractility before ejection fraction (EF) declines. Researchers found that  $\Delta$ GLS at 6 months were predictors of decrease in EF at 12 months (58). And GLS-guided cardioprotective therapy (CPT) prevents reduction in LVEF and development of cardiac dysfunction in high-risk patients undergoing potentially cardiotoxic chemotherapy, compared with usual care (59). Improvements in testing technology have allowed for the emergence of serum biomarkers that play an increasing role in the monitoring of cardiotoxicity. The 2016 ESC Position Paper on cancer treatments and cardiovascular toxicity published by the European Society of Cardiology (ESC) proposed that the use of serum biomarkers

is an important tool for baseline risk assessment and diagnosis of cardiovascular disease. The statement recommends cardiac troponin (CTn) baseline measurement for all cancer patients, as the strongest independent predictor of cardiotoxicity, and in patients with early invasive HER2+ breast cancer undergoing neoadjuvant or adjuvant therapy. B-type natriuretic peptide (BNP)/amino-terminal pro-B-type natriuretic peptide (NT-proBNP) with CTn testing were recommended after receiving trastuzumab (60). In recent years, soluble growth-stimulating expression gene 2 protein (sST2) has received wide attention as a novel heart failure marker. Some studies have shown that sST2 levels correlate with the severity of heart failure, LVEF and NT-proBNP in patients (61). In addition, Zhang et al. (62) analyzed 65 HER2-positive breast cancer patients treated with trastuzumab and applied ordered logistic regression to analyze the relationship between serum miR-222-3p and adverse events and found that serum miR-222-3p was a potential predictor of TIC.

### Choosing an Anthracycline-Free Regimen

In the BCIRG006 clinical trial, the regimen combining anthracyclines with trastuzumab had similar long-term survival rates as the paclitaxel and cyclophosphamide combined with trastuzumab regimen, while the incidence of cardiotoxicity in the latter group was much lower than former (17). A randomized multicenter phase III trial of 438 patients with stage II and III HER2-positive breast cancer showed an estimated 3-year event-free survival rate of 93% in patients treated with anthracyclines and 94% in patients not using, while decrease in LVEF was more common in the anthracycline group (63). This suggests that avoiding anthracyclines when using trastuzumab in favor of other classes of drugs may reduce the likelihood of cardiac events without compromising efficacy.

In addition to its use in combination with chemotherapeutic agents, trastuzumab has shown a good prognosis in combination with other antitumor drugs. Unlike trastuzumab, pertuzumab is a humanized monoclonal antibody against the extracellular structural domain II region of HER2, which inhibits the heterodimerization of HER2 with HER3, thereby blocking pathways including phosphatidylinositol 3-kinase (PI3K/AKT/mTOR) and mitogen-activated protein kinase (RAS/RAF/MEK/ERK) (64, 65). It acts at a different site from trastuzumab in the extracellular structural domain of HER2 and there may be a synergistic effect when they are combined (see **Figure 2**). The NeoSphere phase II study evaluated the efficacy and safety of trastuzumab with pertuzumab in combination with docetaxel in HER2-positive breast cancer patients treated with neoadjuvant therapy, and showed that the dual-target combination chemotherapy significantly increased the pathologic complete remission rate (pCR) as compared to the single-target, while the adverse effects were broadly consistent with the trastuzumab monotherapy arm (66). Furthermore, the TRYPHAENA trial demonstrated that the combination of trastuzumab and pertuzumab, whether co-administered with anthracyclines or with carboplatin, was usually well-tolerated and also showed a higher rate of pCR and a lower incidence of cardiotoxicity in the anthracycline-free trial group (67).

Similarly, the PEONY study demonstrated that dual-targeted combination therapy significantly improved the pCR rate (68). The 2019 NCCN guidelines recommend the TCHP regimen [trastuzumab (H) + pertuzumab (P) in combination with docetaxel (T) + carboplatin (C)] as a first-line treatment option for HER-2-positive breast cancer. This regimen is anthracycline-free and therefore has a higher safety profile for patients with potentially dangerous cardiac function.

## Pharmacological Prevention

Unlike anthracyclines, LVD caused by trastuzumab is usually reversible, thus the ESMO guidelines mainly recommend strategies such as observation and discontinuation of the drug (69). However, a large retrospective cohort study found that discontinuation of trastuzumab led to adverse clinical outcomes (70). Therefore, it is necessary to use appropriate cardioprotective agents in the clinical setting.

## Angiotensin-Converting Enzyme Inhibitor or $\beta$ -Receptor Inhibitors

Early research found that NRG-1/HER signaling regulates myocardial contractility and is influenced by circulating catecholamines and angiotensin-II in animal models (39). This may provide some theoretical basis for the use of ACEI or  $\beta$ -receptor inhibitors in the prevention of TIC. Several small randomized trials and single-center studies have also reported that ACEI and  $\beta$ -blockers ameliorate chemotherapy-induced cardiotoxicity, but these studies all emphasized high-dose anthracycline-induced cardiotoxicity and have limited clinical applicability in TIC (71, 72). In 2016, the MANTICORE 101-Breast randomized clinical trial specifically investigated the pharmacological prevention of TIC and found that Perindopril and Bisoprolol were well-tolerated in the prevention of TIC and attenuated the decrease in LVEF, but trastuzumab-induced left ventricular remodeling was not reversed (73). In another randomized clinical trial, however,

concomitant use of the angiotensin II receptor inhibitor Candesartan did not prevent a reduction in LVEF (74). In 2019, researchers evaluated the preventive effect of Lisinopril and Carvedilol on cardiotoxicity with or without anthracyclines prior to trastuzumab administration and found that both drugs were more protective in patients who had exposure to anthracyclines. Patients receiving pharmacological interventions were more likely to benefit compared to the placebo group [(75); Table 2].

## Statins

A retrospective case control study found that in women with HER2+ breast cancer receiving trastuzumab-based therapy with or without anthracyclines, concomitant statin use was associated with a lower risk of cardiotoxicity (76). And a recent meta-analysis also showed that patients receiving statins during cancer treatment had a lower incidence of cardiotoxicity and were more likely to maintain LVEF during the follow-up period, suggesting that statins have the potential to mitigate the cardiotoxic effects of anthracyclines and trastuzumab (77). Rosuvastatin is a statin with anti-lipid peroxidation effects (78). Kabel et al. (79) found that rosuvastatin had a protective effect against TIC in mice due to the antioxidant and anti-inflammatory properties combined with its ability to induce STAT-3 expression and preserve the morphology of the cardiomyocytes. This study also demonstrated better results in combination with ubiquinone, the oxidized form of coenzyme Q10.

## AMPK Agonist

AMPK (Adenosine 5'-monophosphate (AMP)-activated protein kinase) is considered to be a key regulatory kinase of myocardial energy metabolism (80). Recently, researchers identified mitochondrial dysfunction and altered cardiac energy metabolic pathways as important potential mechanisms of trastuzumab-induced cardiotoxicity (56). Susheel et al. (81) found that low-dose metformin improved mitochondrial function and provided significant myocardial protection against ischemic heart failure by activating AMPK and downstream signaling pathways involving eNOS and PGC-1. Wang et al. (82) observed a heterodimeric shift of AMPK $\alpha$ 2 to AMPK $\alpha$ 1 in the hearts of heart failure patients and mice with transverse artery constriction. They further found that overexpression of AMPK $\alpha$ 2 prevented drug-induced chronic heart failure by increasing mitochondrial phagocytosis and improving mitochondrial function in isolated adult mouse cardiomyocytes. This is consistent with the finding that AMPK agonists (AICAR, metformin) improve trastuzumab-induced symptoms of cardiac insufficiency in IPSC-CMS (56). Although there are no relevant clinical studies to prove whether an AMPK agonist has the function of preventing trastuzumab cardiotoxicity, targeting cellular energy metabolism is a potential research direction. Additionally, it has been shown that activation of AMPK can inhibit the growth of breast cancer cells and increase the sensitivity of breast cancer as well as various other cancers, to chemotherapy and radiotherapy (83). Therefore, it is of great clinical interest to investigate whether AMPK agonists can be used to combat TIC.

**TABLE 2 |** Primary cardiac prevention studies in patients with breast cancer receiving trastuzumab.

References	Enrolled patients	Treatment	Cardiac prevention strategy	Results
Heck et al. (72)	130	Epirubicin ( <i>n</i> = 28 with trastuzumab)	candesartan 32 mg, metoprolol 100 mg, placebo (2 x 2 design)	Absolute LVEF change: 2.6% in placebo, 0.8% in candesartan;
Pituskin et al. (73)	99	Trastuzumab ( <i>n</i> = 22 with doxorubicin)	perindopril 8 mg, bisoprolol 10 mg, placebo (1:1:1)	LVEDVI not different among arms
Boekhout et al. (74)	206	Epirubicin with trastuzumab	candesartan 32 mg, placebo	LVEF decline: 19% in candesartan, 16% in placebo
Guglin et al. (75)	468	Trastuzumab ( <i>n</i> = 189 with doxorubicin)	carvedilol 10 mg, lisinopril 10 mg, placebo	LVEF decline: 32% in placebo, 29% in carvedilol, 30% in lisinopril.

Total flavonoids from Clinopodium Chinense (91)	H9c2 cells Male Sprague-Dawley (SD) rats	200 μM for 24 h 80 mg/kg, i.p. for 15 days	Doxorubicin	↑PI3K/Akt ↑Nrf2/HO-1
Ginkgolide B (92)	H9c2 cells C57BL/10 mice	6.25, 12.5, 25, and 50 μg/ml for 24 h 100 mg/kg, i.p. for 5 days	Doxorubicin	↑PI3K/Akt ↓p38 MAPK
Saponins from leaves of Panax Quinquefolius (93)	H9c2 cells ICR mice	1, 5 and 50 μM for 30 min 125 and 250 mg/kg; p.o. for 15 days	Cisplatin	↓NF-κB ↑PI3K/Akt/GSK-3β
Neferine (94)	H9c2 cells	10 μM for 24 h	Doxorubicin	↑IGF-IR/PI3K/Akt

## Potential Role of Traditional Chinese Medicine on TIC

There are many studies on the prevention and treatment of anthracycline-induced cardiotoxicity in Traditional Chinese Medicine (TCM), but reports regarding TIC are rare. The

inhibition of the NRG1/HER pathway is one of the possible mechanisms of TIC. It has been suggested that activation of Akt may protect cardiac function by inhibiting apoptosis (84). Many active ingredients in Chinese medicine have been reported

to show protective effects against cardiac injury by interfering with the PI3K/Akt signaling pathway, as shown in **Table 3** (85–94). In addition, Zhang et al. (95) used network pharmacology analysis to find that Shenmai injection has multi-target and multi-pathway synergistic effects, which may exert myocardial protective effects through the PI3K-Akt signaling pathway and tumor microRNAs. The Shenmai injection treatment group improved cardiac structure and function, reduced myocardial pathological damage as well as the number of autophagic vesicles in mice compared with the control group. Targeting the inhibition of autophagy by trastuzumab, Liu et al. (96) investigated the protective mechanism of ginsenoside Rg2 against TIC in human cardiac myocytes (HCMs), and found that it could induce autophagy in HCMs by upregulating the expression levels of p-Akt, p-mTOR, Beclin 1, LC3, and ATG5, thus providing protection against TIC. At present, TCM is playing an increasing adjuvant role in the process of cancer treatment, while its role in the prevention and treatment of TIC has yet to be fully explored. Further in-depth studies are of great significance to ensure the safe use of trastuzumab as well as to promote the development of TCM in China.

## SUMMARY AND PROSPECTS

Trastuzumab is a landmark agent in the treatment of HER2-positive breast cancer. It has changed the treatment paradigm for HER2-positive breast cancer patients and has no alternative to its status as a first-line drug for breast cancer. At the same time, its cardiotoxicity remains a major constraint to its use. The mechanism of trastuzumab cardiotoxicity has not been fully elucidated, and there is no specific drug to prevent it in clinical practice. Fewer studies have been conducted specifically on the cardiotoxicity of trastuzumab than on anthracyclines. Researchers should further clarify the mechanism of TIC, establish a reasonable model of myocardial injury, determine

appropriate detection indicators, and conduct research on relevant cardioprotective agents in response to the mechanism in order to provide the possibility of safer use of trastuzumab. In addition, TCM has shown great potential in the prevention of antineoplastic drug-induced cardiotoxicity, and while few studies have been conducted specifically for trastuzumab, this provides a research direction for the prevention and treatment of TIC. There are several hurdles at the clinical study level given that studies evaluating patients treated with trastuzumab alone are lacking, strategies to prevent anthracycline-induced cardiotoxicity are not always applicable to trastuzumab, and the definition and evaluation metrics of cardiotoxicity have yet to be standardized. In clinical application, physicians as well as pharmacists should fully understand the risk factors and fully evaluate basic information such as age, previous cardiovascular history, medication history, and the physical condition of patients before drug administration. In addition, high-risk patients need to be monitored closely throughout the oncology treatment process. These efforts will maximize efficacy while minimizing adverse effects.

## AUTHOR CONTRIBUTIONS

ML and WX assorted information and drafted the manuscript. SW polished the language. YL and CH offered advice about the structure. CL and GL governed the whole process and offered advice. All authors contributed to the article and approved the submitted version.

## FUNDING

This work was supported by Beijing Hope Run Special Fund of Cancer Foundation of China (LC2020L03) and Beijing Municipal Science and Technology Commission (Z181100001618003).

D-Dimer Is a Predictive Factor of  
Cancer Therapeutics-Related Cardiac  
Dysfunction in Patients Treated With  
Cardiotoxic Chemotherapy.  
Front. Cardiovasc. Med. 8:807754.  
doi: 10.3389/fcvm.2021.807754

**Background:** D-dimer is a sensitive biomarker for cancer-associated thrombosis, but little is known about its significance on cancer therapeutics-related cardiac dysfunction (CTRCD).

**Methods:** Consecutive 169 patients planned for cardiotoxic chemotherapy were enrolled and followed up for 12 months. All patients underwent echocardiography and blood test at baseline and at 3-, 6-, and 12 months.

**Results:** The patients were divided into two groups based on the level of D-dimer ( $>1.65 \mu\text{g/ml}$  or  $\leq 1.65 \mu\text{g/ml}$ ) at baseline before chemotherapy: high D-dimer group ( $n = 37$ ) and low D-dimer group ( $n = 132$ ). Left ventricular ejection fraction (LVEF) decreased at 3- and 6 months after chemotherapy in high D-dimer group [baseline, 65.2% (62.8–71.4%); 3 months, 62.9% (59.0–67.7%); 6 months, 63.1% (60.0–67.1%); 12 months, 63.3% (58.8–66.0%),  $p = 0.03$ ], but no change was observed in low D-dimer group. The occurrence of CTRCD within the 12-month follow-up period was higher in the high D-dimer group than in the low D-dimer group (16.2 vs. 4.5%,  $p = 0.0146$ ). Multivariable logistic regression analysis revealed that high D-dimer level at baseline was an independent predictor of the development of CTRCD [odds ratio 3.93, 95% CI (1.00–15.82),  $p = 0.047$ ].

**Conclusion:** We should pay more attention to elevated D-dimer levels not only as a sign of cancer-associated thrombosis but also the future occurrence of CTRCD.

## INTRODUCTION

Recent advances in the diagnosis and treatment of cancers improve its prognosis. However, anticancer drugs, namely, anthracyclines, monoclonal antibodies, tyrosine kinase inhibitors, etc., induce cardiac dysfunction, resulting in poor prognosis in cancer survivors (1). Several cardiac biomarkers and echocardiographic parameters, such as troponins, myeloperoxidase,

interleukin-1 $\beta$  (IL-1 $\beta$ ), Nucleotide-binding domain-like receptor family pyrin domain containing 3, and reduced global longitudinal strain, are proposed to detect the early phase of cancer therapeutics-related cardiac dysfunction (CTRCD) and prompt cardioprotective treatment can improve cardiac function (2–7). Although those parameters are useful, careful monitoring is required for all patients to detect early signs of CTRCD. Thus, a novel biomarker that identifies high-risk patients before chemotherapy is desirable to perform effective clinical monitoring.

D-dimer is a sensitive biomarker for cancer-associated thrombosis, but accumulating evidence suggests that pretreatment D-dimer can be used as a prognostic biomarker for patients with solid tumors (8). In cardiovascular fields, elevated D-dimer is associated with not only thromboembolic events but also heart failure mortality in heart failure patients with reduced and preserved ejection fraction (EF) (9, 10).

Although D-dimer is a promising biomarker in the cardio-oncology field, little is known about the relationship between D-dimer and CTRCD. The present study aimed to evaluate the predictive impact of D-dimer before chemotherapy on the development of CTRCD.

## METHODS

### Study Subjects and Protocol

We enrolled 202 consecutive cancer patients, planned for cardiotoxic chemotherapy, such as anthracyclines, human epidermal growth factor receptor 2 (HER2) inhibitors, tyrosine kinase inhibitors, and proteasome inhibitors, at Fukushima Medical University hospital from November 2016 to March 2019 (Figure 1). Patients were excluded if they died or were transferred to other hospitals within 12 months follow-up period ( $n = 33$ ). The remaining 169 patients were divided into two groups based on the cut-off value of D-dimer, which was defined by the receiver operator characteristic curve analysis to detect the occurrence of CTRCD (Figure 2).

Hypertension was defined as a history of use of an antihypertensive drug or systolic blood pressure of  $\geq 140$  mmHg and/or diastolic blood pressure  $\geq 90$  mmHg. Diabetes was defined as recent use of insulin treatment or hypoglycemic drug or hemoglobin A1c  $\geq 6.5\%$ . Dyslipidemia was defined as a history of use of cholesterol-lowering drugs, or triglyceride was  $\geq 150$  mg/dl, low-density lipoprotein cholesterol was  $\geq 140$  mg/dl, and/or high-density lipoprotein cholesterol was  $\leq 40$  mg/dl. A cumulative dose of anthracycline was expressed as a doxorubicin equivalent (1). HER2 inhibitors included trastuzumab and pertuzumab. Tyrosine kinase inhibitors included dabrafenib, trametinib, lenvatinib, sorafenib, dasatinib, bevacizumab, and pazopanib. Proteasome inhibitors included carfilzomib and bortezomib. Radiation therapy was defined as irradiation to the mediastinum and/or the heart field within the follow-up period. Transthoracic echocardiography and blood sampling test were performed at baseline as well as at 3, 6, and 12 months after the administration of cardiotoxic chemotherapy. All procedures used in this research were approved by the Ethical Committee of Fukushima Medical University.

## Echocardiography

Transthoracic echocardiography was performed by a trained sonographer, and images were checked by another trained sonographer and an echo-cardiologist. We measured cardiac function using EPIQ 7G (Philips Healthtech, Best, The Netherlands). Left ventricular (LV) EF was calculated using the modified Simpson's method according to the guideline from the American Society of Echocardiography and the European Association of Cardiovascular Imaging (11). The LV mass was calculated using the following formula:

**Left ventricular (LV) mass=0.8**

$$\times \left[ 1.04 \times \left\{ \left( \frac{\text{LV diastolic diameter} + \text{interventricular septum wall thickness} + \text{LV posterior wall thickness}}{2} \right)^3 - (\text{LV diastolic diameter})^3 \right\} \right] + 0.6g \quad (11).$$

Cancer therapeutics-related cardiac dysfunction was defined as a decrease in EF by more than 10% points, to a value  $<53\%$  (12). The LV end-diastolic volume index, LV end-systolic volume index, LV mass index, and left atrial volume index were measured using the B-mode ultrasound.

## Blood Sampling

High sensitivity cardiac troponin I (TnI) was measured using an assay based on Luminescent Oxygen Channeling Immunoassay technology and run on a Dimension EXL Integrated Chemistry System (Siemens Healthcare Diagnostics, Deerfield, IL, USA). B-type natriuretic peptide (BNP) levels were measured using a specific immunoradiometric assay (Shionoria BNP kit, Shionogi, Osaka, Japan). D-dimer was measured using a latex agglutination method (Lias Auto D-dimer Neo, Sysmex, Kobe, Japan).

## Statistical Analysis

All statistical analyses were performed using Prism 9 (GraphPad Software, San Diego, CA, USA) or R software packages version 3.6.3 (R core team 2020, Vienna, Austria). We used the Shapiro-Wilk test to discriminate which variables were normally or not normally distributed. Normally distributed variables were shown as mean  $\pm$  SD. Non-normally distributed variables were indicated by a median with interquartile range. Category variables were shown in numbers and percentages. Student's  $t$ -test was used for variables following a normal distribution, the Mann-Whitney U-test was used for variables of the non-normal distribution, and the chi-square test was used for categorical variables. The time course of EF (baseline, 3-, 6-, and 12 months after the administration of anthracyclines) was evaluated using the Friedman test.

Logistic regression analysis was performed to identify the variables to predict the occurrence of CTRCD. We selected variables relating to the general condition and cardiac function, i.e., age, echocardiographic parameters, use of anthracyclines, BNP, hemoglobin, estimated glomerular filtration ratio, and the elevation of D-dimer. The variables presenting  $p < 0.05$  in the

univariable analysis were entered into the multivariable analysis. A receiver operating characteristic curve analysis was performed to determine the optimal cut-off value of the D-dimer for predicting the occurrence of CTRCD. The *p* of 0.05 or less was defined as significant.

## RESULTS

First, we performed a receiver operating characteristic curve analysis to identify the threshold level of D-dimer to predict the occurrence of CTRCD (**Figure 2**). A total of 12 patients suffered from CTRCD within 12 months follow-up period. When we set the cut-off value of D-dimer at 1.65 µg/ml, sensitivity, specificity,

and area under the curve to predict CTRCD were 50.0%, 80.3%, and 0.661, respectively. Then, we divided the patients into two groups based on the cut-off value. **Table 1** shows patient characteristics at the baseline before chemotherapy. There were no statistical differences in age, sex, and the usage of angiotensin-converting enzyme inhibitors/angiotensin II receptor blockers and  $\beta$ -blockers. The high D-dimer group included a lower rate of breast cancer (35 vs. 67%, *p* = 0.0005), a higher rate of ovarian/uterine cancer (19 vs. 6%, *p* = 0.0151), and a higher rate of leukemia (16 vs. 4%, *p* = 0.0068) than low D-dimer group. Echocardiographic data demonstrated that EF was slightly higher in the high D-dimer group ( $67 \pm 5$  vs.  $64 \pm 5\%$ , *p* = 0.0019). In laboratory data, the high D-dimer group showed lower hemoglobin values and higher BNP values.

Time-dependent changes in EF are displayed in **Figure 3**. Low D-dimer group showed no changes in EF within the follow-up period, but EF was decreased at 3- and 6 months after chemotherapy in high D-dimer group [baseline, 65.2% (62.8–71.4%); 3 months, 62.9% (59.0–67.7%); 6 months, 63.1% (60.0–67.1%); 12 months, 63.3% (58.8–66.0%), *p* = 0.03, **Figures 3A,B**]. The reduction of EF from baseline was larger in high D-dimer group than in low D-dimer group (3 months:  $-4.0 \pm 7.1$  vs.  $-0.5 \pm 5.3$ , *p* = 0.0015; 6 months:  $-4.8 \pm 8.0$  vs.  $-0.2 \pm 6.2$ , *p* = 0.0004; 12 months:  $-4.5 \pm 7.3$  vs.  $-0.4 \pm 6.6\%$ , *p* = 0.0024).

The occurrence of CTRCD during the 12-month follow-up period was higher in the high D-dimer group than in the low D-dimer group (16.2 vs. 4.5%, *p* = 0.0146). Multivariable logistic regression analysis revealed that LV end-diastolic volume index [odds ratio 0.95, 95% CI (0.91–0.99), *p* = 0.0122] and high D-dimer levels [odds ratio 3.93, 95% CI (1.00–15.82), *p* = 0.0469] before chemotherapy were independent predictors of the development of CTRCD (**Table 2**).

## DISCUSSION

In the present study, we revealed the predictive features of D-dimer in patients treated with cardiotoxic agents. First, the threshold level of D-dimer was 1.65  $\mu$ g/ml to predict the development of CTRCD. Second, EF was decreased time-dependently in high D-dimer patients. Third, the occurrence of CTRCD was significantly higher in high D-dimer patients.

D-dimer is a pivotal biomarker of hypercoagulability and thrombosis. Fibrin-bound plasmin degrades the fibrin network into soluble fragments D-dimers and E fragments, thus increased levels of D-dimer represent a global activation of coagulation and fibrinolysis (13). Cancers produce hypercoagulable and prothrombotic situations by secreting several pro-thromboembolic factors, such as mucins, cysteine protease, and tissue factors (14). Therefore, thrombi are easily generated in patients with cancer, and thromboembolism is the second

**TABLE 2 |** Parameters associated with the occurrence of CTRCD.

	Univariate		Multivariate	
	OR (95% CI)	P-value	OR (95% CI)	P-value

CTRCD, cancer therapeutics-related cardiac dysfunction; BNP, B-type natriuretic peptide; E/A, early to late diastolic transmitral flow velocity; LV, left ventricular; GFR, glomerular filtration ratio.

leading cause of cancer-related morbidity and mortality (15, 16). Although D-dimer is an established and widely used biomarker for the screening of thrombus formation in patients with cancer, prognostic features of D-dimer have become clinically overt recently. The link between D-dimer and cancer progression is reported in several papers (17, 18), and higher levels of D-dimer are associated with poor prognosis in cancer patients (18). Although the precise mechanisms are still complex and uncovered, the pro-coagulable state may produce a suitable milieu for cancer progression by recruitment of pro-metastatic leukocytes, adhesion to the endothelium, transendothelial migration, and restriction in natural killer cell-mediated clearance of micrometastasis (19, 20). Accumulating evidence showed that abnormal inflammation and oxidative stress are key factors to the development of heart failure, and these also play important roles in cancer progression and thrombus formation (21–25). For example, IL-1 $\beta$ , a representative inflammatory cytokine, induces cardiac dysfunction and thrombus formation (26). IL-1 $\beta$  activates myddosome complex, such as nuclear factor  $\kappa$ B, myeloid differentiation factor 88, cryopyrin, and p38-MAPK, in cardiomyocytes, leading

to dysregulates metabolism in the sarcoplasmic reticulum, calcium homeostasis, and myocardial apoptosis and necrosis (7). In addition, IL-1 $\beta$  increased pro-coagulant state through activating tissue factor-dependent mechanisms in endothelial cells (27). Gomes et al. reported that blockade of IL-1 receptor abolished the neutrophil extracellular traps-dependent pro-thrombotic state and attenuated cancer-associated thrombosis in murine breast cancer model (25). Considering the fact that inflammation is a major contributor to cardiac dysfunction and thrombus formation, cancer patients with high D-dimer may be predisposed to cardiac dysfunction due to a chronic inflammatory state. Cardiotoxic chemotherapeutic agents are crucial and indispensable to performing cancer treatment. Anthracyclines induce pro-inflammatory responses by increasing tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ), IL-1 $\beta$ , and IL-6, leading to tumor cell death (28). Not only anthracyclines but also targeted chemotherapy, such as trastuzumab and bevacizumab, increased inflammatory cytokines after the treatment (29, 30). In the present study, the patients with a high D-dimer group may already have been exposed to an inflammatory state before chemotherapy and were vulnerable to additional inflammatory

stress by cardiotoxic agents, resulting in the development of CTRCD. To elucidate the precise mechanisms was beyond this study, but the importance of D-dimer should be noted in the cardio-oncology field. Intervention with Pravastatin in Ischemic Disease (LIPID) study revealed that elevated D-dimer levels predict long-term risk of arterial and venous events, cardiovascular disease mortality, in addition to that, increased cancer incidence and mortality rate (31). To the best of our knowledge, this is the first report assessing the relationship between D-dimer levels and the development of CTRCD. The importance of D-dimer should be taken into account when managing patients with cancer who are treated with cardiotoxic chemotherapy.

## LIMITATION

This study has several limitations. First, this study was performed using a relatively small number of patients and a short follow-up period by a single center. Slight differences in EF at baseline may be due to the small sample size of the high D-dimer group. Second, although not statistically significant, a higher proportion of patients in the high D-dimer group received anthracycline-containing chemotherapies. This might affect the results in the reduction in EF in the high D-dimer group. Longer follow-up and larger population data were needed to confirm the importance of D-dimer to the development of CTRCD and cardiovascular prognosis. Third, D-dimer has modest sensitivity and specificity to predict CTRCD in the present study. The mechanisms by which CTRCD development must be complicated, thereby predicting CTRCD by a single biomarker is still challenging. D-dimer is frequently analyzed in daily clinical practice to detect cancer-associated thrombosis. Therefore, we think D-dimer is easy and useful for predicting both CTRCD and thrombus formation.

## CONCLUSION

Elevated D-dimer is a pivotal biomarker to predict CTRCD. D-dimer should be taken into account when managing cancer patients treated with cardiotoxic chemotherapy.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Ethical Committee of Fukushima Medical University Hospital. The patients/participants provided their written informed consent to participate in this study.

## AUTHOR CONTRIBUTIONS

MO created the study design, analyzed the data, and drafted the manuscript. DY created the study design and analyzed the data. TM, TS, TK, and AK acquired the data. AY, KN, TI, and YT interpreted the data and revised the manuscript. All authors contributed to the conception, design, critical revision, and final approval of this manuscript.

Doxorubicin (DOX) is an extremely effective and wide-spectrum anticancer drug, but its long-term use can lead to heart failure, which presents a serious problem to millions of cancer survivors who have been treated with DOX. Thus, identifying agents that can reduce DOX cardiotoxicity and concurrently enhance its antitumor efficacy would be of great clinical value. In this respect, the classical antidiabetic drug metformin (MET) has stood out, appearing to have both antitumor and cardioprotective properties. MET is proposed to achieve these beneficial effects through the activation of AMP-activated protein kinase (AMPK), an essential regulator of mitochondrial homeostasis and energy metabolism. AMPK itself has been shown to protect the heart and modulate tumor growth under certain conditions. However, the role and mechanism of the hypothesized MET-AMPK axis in DOX cardiotoxicity and antitumor efficacy remain to be firmly established by *in vivo* studies using tumor-bearing animal models and large-scale prospective clinical trials. This review summarizes currently available literature for or against a role of AMPK in MET-mediated protection against DOX cardiotoxicity. It also highlights the emerging evidence suggesting distinct roles of the AMPK subunit isoforms in mediating the functions of unique AMPK holoenzymes composed of different combinations of isoforms. Moreover, the review provides a perspective regarding future studies that may help fully elucidate the relationship between MET, AMPK and DOX cardiotoxicity.

**Keywords:** doxorubicin, metformin, AMPK, doxorubicin cardiotoxicity, cardio-oncology

## INTRODUCTION

The anthracycline doxorubicin (DOX) has been widely used for over 5 decades and is a highly effective chemotherapeutic agent for the treatment of a broad spectrum of cancers including various solid tumors and leukemia. Unfortunately, DOX chemotherapy can cause severe cardiotoxic effects (1–3). Acute toxicity occurs immediately after treatment and is generally transient. Chronic cardiotoxicity is more serious and culminates in irreversible congestive heart failure. Currently, only the iron chelator dexrazoxane has been approved for limited clinical use for reducing DOX cardiotoxicity in certain pediatric or breast cancer patients (4–7). Given the continuing widespread use of DOX in cancer chemotherapies, it is imperative to identify

new strategies that can protect against DOX cardiotoxicity without compromising the anti-tumor activity of DOX. Metformin (MET), a drug used for the first-line treatment of type 2 diabetes, has been suggested as such a dual-function agent that can simultaneously decrease DOX cardiotoxicity (8–11) and increase its anticancer activity (12, 13). The differential effects of MET on cardiomyocytes and cancer cells may be related to the differences in cellular energy metabolism. Cardiomyocytes are highly dependent on mitochondria for energy supply, while cancer cells primarily use glycolysis-generated ATP. Therefore, drugs such as MET that modulate mitochondrial function may have substantially different effects on the heart as compared to tumors. AMP-activated protein kinase (AMPK), a cellular energy sensor, is activated by MET and implicated in both cardioprotection and tumor growth. Most cell-based studies have suggested AMPK as a downstream effector of MET that functions to reduce DOX cardiotoxicity (9, 11, 14–17). However, the role of AMPK in cancer has been controversial (18). It remains uncertain whether and how AMPK affects the ability of MET to modulate DOX cardiotoxicity or tumor growth *in vivo*. This mini-review will extract evidence from currently available literature for or against a role of AMPK in MET-mediated protection against DOX cardiotoxicity. For the effects of MET and AMPK in antitumor therapies, the readers are referred to other review articles published elsewhere (18–24).

## DOX CARDIOTOXICITY IS A SERIOUS CLINICAL PROBLEM

DOX is an extremely effective and wide-spectrum antineoplastic drug that can lead to dose-dependent cardiotoxicity, culminating in heart failure (1–3). This presents a serious problem to millions of cancer survivors who have been treated with DOX. Indeed, the cardiovascular mortality in cancer survivors exceeds that caused by cancer *per se* (25). DOX cardiotoxicity is even more significant in childhood cancer since about half of all pediatric patients are treated with anthracyclines and many childhood cancer survivors go on to develop cardiac dysfunction (26–28). Due to the dose-dependent risk, the lifetime cumulative dose of DOX has been recommended not to exceed 450 mg/m<sup>2</sup> per patient (1). Thus, DOX cardiotoxicity is a significant life-long health concern for cancer survivors.

## DOX INDUCES CARDIOTOXICITY VIA MULTIPLE MECHANISMS

Several mechanisms have been proposed to account for the ability of DOX to produce cardiotoxicity. DOX is concentrated in the mitochondria and its quinone moiety is reduced by the oxidoreductases to a semiquinone form which in turn donates its excess electron to O<sub>2</sub>, leading to the formation of reactive oxygen species (ROS) including superoxide anions (29, 30).

**Abbreviations:** DOX, doxorubicin; MET, metformin; ROS, reactive oxygen species; AMPK, AMP-activated protein kinase; TOPII $\alpha$ / $\beta$ , topoisomerase II $\alpha$ / $\beta$ ; ACE, angiotensin-converting enzyme; IGF1, Insulin-like growth factor 1; P-gp, P-glycoprotein; LKB1, Liver Kinase B1; MEFs, mouse embryonic fibroblasts.

Although the long-held ROS and oxidative stress theory of DOX cardiotoxicity is strongly supported by numerous animal studies (31–33), clinical trials have failed to demonstrate the efficacy of antioxidant supplements in reducing DOX-triggered cardiac injury (34, 35), suggesting that oxidative stress is not the only mechanism that mediates DOX cardiotoxicity. Interestingly, DOX has been shown to either bind with free iron (36) or cause mitochondrial iron accumulation in the heart (37), which may directly cause mitochondria-dependent ferroptosis or produce additional ROS intensifying the oxidative stress (38). The contribution of iron to DOX cardiotoxicity is demonstrated by the ability of the iron chelator dexrazoxane to attenuate DOX-induced cardiomyopathy (4, 5, 37). Another recognized culprit of DOX cardiotoxicity is mitochondrial dysfunction (39). Being the major site of DOX-induced ROS production, mitochondria themselves are vulnerable to oxidative injury. DOX interacts with the acidic lipoprotein cardiolipin in the inner mitochondrial membrane, resulting in its peroxidation and the opening of mitochondrial permeability transition pores which in turn triggers cytochrome c release and apoptosis (40, 41). The third mechanism proposed for DOX cardiotoxicity is through its effect on topoisomerase II $\beta$  (TOPII $\beta$ ). While the antitumor effect of DOX is through DNA intercalation and TOPII $\alpha$  inhibition (42–44), DOX also binds to TOPII $\beta$  which is expressed mainly in quiescent cells such as cardiomyocytes. Mice null for TOPII $\beta$  do not exhibit cardiotoxic effects with DOX treatment (45), suggesting that TOPII $\beta$  is a major mediator of DOX cardiotoxicity. DOX is proposed to complex with TOPII $\beta$ , leading to the activation of p53 mediated DNA damage pathways and the inhibition of genes implicated in mitochondrial biogenesis. Interestingly, dexrazoxane is shown to protect the heart by transiently depleting TOPII $\beta$  levels in cardiomyocytes, suggesting that dexrazoxane may reduce DOX cardiotoxicity via both TOPII $\beta$  depletion and iron chelation (46). The last potential mechanism of DOX cardiotoxicity relates to autophagy, a catabolic process for the cell to degrade long-lived proteins and organelles in the lysosome. The exact function of autophagy in DOX cardiotoxicity remains hotly debated, which is not surprising given the dynamic nature of the multi-step autophagic process and the numerous pathways implicated in its regulation. Indeed, DOX has been shown to either activate autophagy (17, 47–50) or inhibit autophagy (51–53), paradoxically, both of which contribute to cardiotoxicity. Adding to the confusion, DOX-triggered suppression of autophagy is seemingly cardioprotective (54). These conflicting results may be attributable to the differences in the experimental models used, the developmental stages of cardiomyopathy, and the dose and duration of DOX treatment, as well as the methods applied to manipulate different steps of the autophagic process and the techniques used to measure autophagic activities (49, 55). An early sign of DOX-induced mitochondrial damage is the loss of mitochondrial membrane potential (56–58). The latter is a major mechanism that triggers mitochondrial degradation by autophagy, a process known as mitophagy. However, as with autophagy, it remains controversial whether DOX activates or inhibits mitophagy and whether mitophagy contributes to or protects against DOX cardiotoxicity (59–62).

Further investigation is needed to measure mitophagy flux and elucidate the role of mitophagy in DOX cardiotoxicity by using more reliable approaches and more clinically relevant animal models. In summary, it is likely that DOX induces cardiotoxicity via multiple mechanisms, including ROS generation, iron accumulation, cardiolipin peroxidation/mitochondrial injury, topoisomerase binding, and autophagy/mitophagy dysfunction (Figure 1).

## NEW STRATEGIES TO DIMINISH DOX CARDIOTOXICITY IN CANCER PATIENTS ARE DESPERATELY NEEDED

The current approach for reducing DOX cardiotoxicity is to limit the overall cumulative dose of the drug. However, this also narrows the therapeutic window for cancer treatment. Other strategies for limiting its cardiotoxicity have been pursued. Attempts to develop chemical analogs that retain anti-tumor properties but have reduced cardiotoxicity have had minimal success (63). Liposomal DOX has improved pharmacokinetics and reduced accumulation in the heart (64) but has failed to replace conventional DOX for treatment of most solid tumors (65). An additional approach is to combine DOX with a cardioprotective agent during treatment. Common neurohormonal antagonists, such as β-adrenergic receptor blockers and angiotensin-converting enzyme inhibitors, are routinely used for treating non-cancer-related heart failure, but they are not recommended for preventing and managing DOX cardiotoxicity due to the marginal benefits and related adverse events (66). Currently, only the iron chelator dexrazoxane has been approved for clinical use for reducing DOX cardiotoxicity (4, 5). Unfortunately, dexrazoxane is not a ubiquitous treatment for anthracycline cardiotoxicity, and its use has been limited to pediatric patients with high risk acute lymphoblastic leukemia

and breast cancer patients on high doses of DOX, given the possibility of dexrazoxane to cause myelosuppression and secondary malignancies (6, 67, 68). Therefore, it is imperative to develop new strategies to protecting against DOX-induced heart damage without compromising the anti-tumor activity of DOX. In this regard, the antidiabetic drug metformin (MET) has appeared to be such a promising dual-function agent that can improve the clinical use of DOX.

## METFORMIN PROTECTS THE HEART AGAINST VARIOUS PATHOLOGICAL CONDITIONS INCLUDING DOX CARDIOTOXICITY

Metformin (MET) is an oral biguanide agent that was first utilized to treat diabetes in France in 1957 (69) and approved by the US FDA in 1994 and has since been widely used as the first-line treatment for Type II diabetes due to its safety, efficacy and tolerability (70, 71). MET has been shown to protect the heart in people with or without diabetes mellitus (72). Indeed, MET is associated with decreased risk of heart failure (73) and reduced cardiovascular mortality independent of its glucose lowering effects (74). The cardioprotective effects of MET have been repeatedly confirmed by numerous pre-clinical studies under various cardiac conditions (75–79). Not surprisingly, MET can also reduce DOX cardiotoxicity in many animal studies (8–11). This may hold true in humans as well, given the ability of MET to attenuate radiation cardiotoxicity in breast cancer patients (80). Unfortunately, a phase II clinical trial “Use of Metformin to Reduce Cardiac Toxicity in Breast Cancer” was prematurely terminated due to its failure to meet target accrual (<https://clinicaltrials.gov/ct2/show/NCT02472353>). Apparently, further clinical trials are needed to confirm the cardioprotective effects of MET in cancer patients

treated with DOX. MET has been suggested to antagonize DOX cardiotoxicity through several mechanisms (left panel in **Figure 2**), including attenuation of ROS generation and oxidative stress, inhibition of mitochondrial damage and maintenance of energy production (82), normalization of autophagy markers (8), increased expression of ferritin heavy chain in cardiomyocytes, and activation of AMP-activated protein kinase (AMPK) (11). The role of AMPK in MET-induced protection against DOX cardiotoxicity has been supported by numerous studies either in cultured cells or in animals (8–11).

## METFORMIN HAS ANTITUMOR PROPERTIES THAT MAY SYNERGIZE WITH THE ANTITUMOR ACTIVITY OF DOX

Several epidemiological studies, meta-analyses and animal studies have revealed that MET has anti-neoplastic and chemopreventive activities (20, 81) despite mixed results observed in other studies (82, 83). Indeed, diabetic patients

taking MET have significantly reduced risk of cancer and lower cancer-related mortality (84–89). Several small-scale clinical trials have shown the ability of MET to induce favorable cellular and molecular changes in cancer patients (90–93). For example, clinical trials in pre-surgical endometrial cancer patients exhibited a significant decrease in Ki67 with MET monotherapy (19). Another study showed the ability of MET to inhibit the increase of Insulin-like growth factor 1 (IGF-1) and maintain the levels of IGF binding protein-1 although the progression-free survival was not affected (91). In addition, numerous animal studies have shown that MET can enhance the anticancer activity of DOX (11–13, 94, 95). Thus, it is highly desirable that large scale randomized clinical trials be conducted to confirm the usefulness of MET in cancer chemotherapy. Nevertheless, given the demonstrated anti-tumor and cardioprotective properties of MET, it is reasonable to believe that MET can be used in DOX-containing chemotherapy to enhance the antitumor activity of DOX and at the same time to reduce its cardiotoxic effect (96). Metformin is believed to exert its antitumor effects via multiple mechanisms (right panel in

**Figure 2**), including activation of AMPK and inhibition of mTOR (13, 97, 98), reduction of blood glucose (21), reduction of insulin and IGF-1(98), inhibition of cancer stem cells (99), modulation of adenosine A1 receptor (100), down-regulating drug-resistant gene P-glycoprotein (P-gp) (94), inhibition of midkine (101), and induction of apoptosis (102, 103). Among them, AMPK activation has been suggested to be the major mechanism that mediates both the anti-tumor and cardioprotective effects of metformin (11, 13, 21, 97). If this is true, modulation of AMPK *per se* should improve the application of DOX in antitumor therapy.

## AMPK SIGNALING MAY PROTECT AGAINST DOX CARDIOTOXICITY

AMP-activated protein kinase (AMPK) is a heterotrimeric protein kinase composed of a catalytic  $\alpha$  subunit and two regulatory subunits ( $\beta$  and  $\gamma$ ). Each subunit has multiple isoforms encoded by distinct genes ( $\alpha 1$ ,  $\alpha 2$ ,  $\beta 1$ ,  $\beta 2$ ,  $\gamma 1$ ,  $\gamma 2$ , and  $\gamma 3$ ), and they combine to form 12 different AMPK holoenzymes (104). All isoforms except for  $\gamma 3$  are expressed in mouse and human heart, which can form 8 AMPK holoenzymes (105). As an energy sensor, AMPK detects and reacts to fluctuations in intracellular ATP levels under normal and stress conditions. The activated AMPK affects multiple metabolic pathways to maintain an energy homeostasis conducive to stress resistance and cell survival (106). There has been continuous intense research targeting AMPK for the treatment of multiple prevalent diseases, such as obesity, diabetes, cancer and cardiovascular diseases (107–109). Using AMPK deficient mice and chemical activators of AMPK such as AICAR and MET, numerous studies have shown that AMPK exerts a cardioprotective effect against myocardial ischemic injury (110, 111), diabetic cardiomyopathy (112), pathological cardiac remodeling (113), and heart failure (109). However, the use of MK-8722, a pan-AMPK activator, induces cardiac hypertrophy despite its ability to improve glucose homeostasis in rodents and rhesus monkeys (114), casting some doubt on the notion that AMPK activation always benefits the heart. Indeed, the gain-of-function mutations of the AMPK  $\gamma 2$  subunit result in severe cardiomyopathy in humans (115, 116), suggesting that the activation of some AMPK isoforms or holoenzymes can be detrimental to the heart under certain conditions. Interestingly, AMPK holoenzymes containing the  $\alpha 2$  rather than the  $\alpha 1$  subunit are the primary mediators of the cardiac phenotype of  $\gamma 2$  mutations (117), suggesting that  $\alpha 1$ -AMPK may play a different role than  $\alpha 2$ -AMPK, which underscores the complexity of isoform-specific functions of AMPK. This isoform-specific phenomenon was also observed in skeletal muscle where  $\alpha 2$  but not  $\alpha 1$  AMPK is responsible for AICAR-induced glucose uptake (118). When it comes to DOX cardiotoxicity, most cell-based studies have suggested AMPK as cardioprotective (9, 11, 14–17) despite the fact that DOX has been reported to either increase or decrease cardiac AMPK activity depending on the dose and duration of DOX treatment as well as the experimental models used (59, 119, 120). Pharmacological agents including MET, statins and many others

can simultaneously activate AMPK and protect against DOX cardiotoxicity, but this remains an association and the causality between these two effects has not been established (119, 120). For example, the proposed role of AMPK in MET-mediated protection against DOX cardiotoxicity remains to be determined by using genetic animal models lacking AMPK function. Also, it remains essentially unknown which of the 8 isoform-specific AMPK holoenzymes mediates the putative protective effects on DOX cardiotoxicity *in vivo*.

## AMPK PLAYS TEMPORAL AND ISOFORM-DEPENDENT DICHOTOMOUS ROLES IN CANCER

AMPK is considered to be both a tumor suppressor and an oncogene depending on the context (22). Studies have suggested AMPK as a tumor suppressor before disease arises, which is further enhanced by the biguanide phenformin. However, once cancer has occurred, AMPK becomes a tumor promoter to enhance cancer cell survival by protecting against metabolic, oxidative and genotoxic stresses (23). Indeed, the Liver Kinase B1 (LKB1)/AMPK pathway contributes to tumor cell survival by promoting cellular sensing of and adaptation to bioenergetic stress. Repression of LKB1 by miR-17~92 sensitizes MYC-dependent lymphoma to biguanide treatment (121). In addition, a loss of both AMPK  $\alpha 1$  and  $\alpha 2$  subunit isoforms in H-Ras-transformed mouse embryonic fibroblasts (MEFs) caused a complete failure of their growth *in vivo* in immunodeficient mice (122). However, a loss of AMPK  $\alpha 2$  alone caused the tumors to grow more rapidly (123), suggesting isoform-dependent differential effects of AMPK on tumor growth. In summary, whether AMPK behaves as a tumor suppressor or a promoter depends on the developmental stage of the tumor and the specific isoform of the AMPK subunits.

## MET ACTIVATES AMPK, BUT IT IS UNKNOWN IF AMPK IS RESPONSIBLE FOR CARDIOPROTECTION BY MET

Met has been shown to activate the AMPK pathway, and this has been proposed as the major mechanism that mediates the cardioprotective (9, 11, 109, 119, 120) and antitumor (13, 96, 97, 124) effects of MET. Thus, pharmacologically activating the AMPK pathway seems to be a two-birds-with-one-stone strategy to simultaneously reduce DOX cardiotoxicity and enhance its antitumor activity. However, it remains to be determined whether AMPK is indeed responsible for the potential double benefits of MET in humans or in clinically relevant animal models. Indeed, MET is shown to reduce pathological cardiac remodeling in the absence of AMPK $\alpha 2$  (76), suggesting the possibility that MET may reduce DOX cardiotoxicity independently of AMPK. Given the dual role of AMPK in tumor growth, it is equally unclear if the antitumor effects of MET are mediated by AMPK or its subunit isoforms.

## SUMMARY AND FUTURE PERSPECTIVES

MET has been safely used to treat diabetes for several decades, making it a good candidate for repurposing (19). Indeed, many animal and preclinical studies suggest that MET has both cardioprotective and antitumor properties, which lends itself as a promising adjuvant drug for DOX anticancer therapies to reduce cardiotoxicity. MET is proposed to achieve these beneficial effects through the activation of AMPK that itself has been shown to protect the heart and modulate tumor growth under certain conditions. However, the role and mechanism of the hypothesized MET-AMPK axis in DOX cardiotoxicity and antitumor efficacy have not been firmly established. Convincing *in vivo* studies using tumor-bearing animal models and large-scale prospective clinical trials are needed to fully establish MET as an effective antitumor agent either alone or together with DOX. Also, the proposed role of AMPK in MET-mediated protection against DOX cardiotoxicity should be validated in genetic animal models lacking AMPK in the heart. Given the emerging evidence suggesting distinct functional roles of the AMPK isoforms, it is important to investigate how different AMPK holoenzymes containing unique combinations of isoforms will modulate the ability of DOX to affect either heart function or tumor growth. Future studies should also explore the cellular and molecular mechanisms that account for the differential responses of cardiomyocytes vs. cancer cells to DOX and MET, either individually or in combination. Without any doubt, answers to the above questions are expected to have a positive impact on the treatment of many types of cancers with DOX. For example, if it is firmly established that MET

can reduce DOX cardiotoxicity and concurrently maintain its antitumor activity, the results could be rapidly translated into use for cancer patients because MET has been used in diabetic patients for decades. Specifically, including MET in a therapeutic protocol could reduce the amount of DOX needed to achieve the same antitumor effect. Alternatively, MET could make it possible to use larger doses of DOX to eradicate cancer more effectively without increasing cardiac damage. In short, MET could improve the therapeutic window for DOX, allowing greater flexibility in designing regimens for treating cancer. Finally, a comprehensive understanding of the relationship between DOX cardiotoxicity, antitumor efficacy, and individual isoforms of AMPK will guide novel mechanism-based therapeutic strategies that target AMPK.

## AUTHOR CONTRIBUTIONS

ManrS, AN, JD, JW, MandS, and TN contributed to sections of the first draft. SK made the figures and edited the manuscript. QL wrote the outline, edited the draft, and finalized the manuscript. All authors contributed to the article and approved the submitted version.

## FUNDING

This line of research in the laboratory was supported by an in-house grant from New York Institute of Technology College of Osteopathic Medicine (NYITCOM) to QL and a research grant from the American Osteopathic Association (AOA, #2007816) to TN.

Cardio-oncology requires a good knowledge of the cardiotoxicity of anticancer drugs, their mechanisms, and their diagnosis for better management. Anthracyclines, anti-vascular endothelial growth factor (VEGF), alkylating agents, antimetabolites, anti-human epidermal growth factor receptor (HER), and receptor tyrosine kinase inhibitors (RTKi) are therapeutics whose cardiotoxicity involves several mechanisms at the cellular and subcellular levels. Current guidelines for anticancer drugs cardiotoxicity are essentially based on monitoring left ventricle ejection fraction (LVEF). However, knowledge of microvascular and metabolic dysfunction allows for better imaging assessment before overt LVEF impairment. Early detection of anticancer drug-related cardiotoxicity would therefore advance the prevention and patient care. In this review, we provide a comprehensive overview of the cardiotoxic effects of anticancer drugs and describe myocardial perfusion, metabolic, and mitochondrial function imaging approaches to detect them before over LVEF impairment.

**Keywords:** cardio-oncology, cardiotoxicity, perfusion, metabolism, mitochondria, magnetic resonance spectroscopy or MRS, magnetic resonance imaging, nuclear imaging

## INTRODUCTION

Cancer therapy significantly improves patient survival but is sometimes accompanied by cardiotoxic effects. Cardiotoxic complications can range from myocardial abnormalities, valvular abnormalities, pericardial diseases, coronary artery disease (CAD), and alteration in left ventricle ejection fraction (LVEF).

Anthracyclines, one of the most used and oldest chemotherapies, are the archetypal cardiotoxic anticancer drug, ultimately leading to the heart failure (1). In addition, the emerging field of cardio-oncology has seen the development of new anticancer drugs such as antiangiogenics also leading to cardiotoxicity with endothelial dysfunction, forcing a reconsideration of the stages, timing, and levels of cardiotoxicity.

Initial evaluation of LVEF and subsequent evaluation under anticancer therapy is paramount as the most guidelines for cardiotoxicity are based on LVEF impairment (2). To date, echocardiography remains the most frequently used method to detect LVEF alteration, but also

by assessment of left ventricle (LV) longitudinal strain evaluation that might identify early LVEF dysfunction (3). Although not considered the first-line method, cardiac magnetic resonance imaging (CMR) can assess cardiac anatomy, structure, and tissue properties in addition to LVEF.

These modalities have been able to detect impaired cardiac function in the later stages of cardiac side effects (4). Myocardial perfusion imaging and metabolic imaging are powerful approaches providing novel biomarkers that can improve early detection of cardiotoxicity before irreversible cardiac damage occurs. This review summarizes the alterations in cardiac perfusion and metabolism that occur in anticancer drug-related cardiotoxicity and the advantage of assessing perfusion and metabolism non-invasively in the beating heart with cardiac imaging.

## MYOCARDIAL VASCULAR AND METABOLIC EFFECTS OF ANTICANCER DRUGS

### Overview of the Link Between Myocardial Circulation and Metabolism

There is a close relationship between myocardial blood circulation, which delivers oxygen and nutrients, tissue metabolism, and oxidative stress. The heart has a very high energy demand to sustain contractile function and synthesizes adenosine triphosphate (ATP) through oxidative metabolism of free fatty acids (FFA), glucose, ketones, and lactate (5).

The adult heart normally obtains 50–70% of its ATP from fatty acid  $\beta$ -oxidation in the presence of oxygen. However, it must adapt, switching from one substrate to another, to sustain demand depending upon the metabolic state and physical conditions at the time (5). Under well-perfused aerobic conditions, glucose and FFA are catabolized into pyruvate or acyl-CoA, respectively, both of which are catabolized to acetyl-CoA to enter the tricarboxylic acid (TCA, Krebs) cycle. Most of the energy supply is then derived from the mitochondrial oxidative phosphorylation system. The main cardiac energy reserve is phosphocreatine (PCr), which is maintained by the following creatine kinase (CK) reaction:

This system facilitates intracellular delivery of energy from mitochondria to cytoplasmic sites of ATP utilization and maintains a high level of ATP during changes in energy demand (6).

Direct damage to the mitochondria, blood supply, and myocardial metabolism will be responsible for abnormal production of reactive oxygen species (ROSs). ROS are reactive intermediates of the molecular oxygen that are essentially generated during mitochondrial oxidative phosphorylation (7). Cellular sources of ROSs are cardiomyocytes, endothelial cells, stromal cells, and inflammatory cells in the heart (8). One of the major ROSs is the proximal mitochondrial ROSs (superoxide anion), which can be generated by a loss of ATP production or when there is a high NADH/NAD<sup>+</sup> ratio in the mitochondrial

matrix (9). An imbalance between ROS production and antioxidant cell response leads to endothelial dysfunction, the release of proinflammatory cytokines, and vasoconstriction of epicardial and microvascular coronary arteries (10). The heart is particularly sensitive to oxidative stress because of its low-antioxidant resources (11–13). One of the main mechanisms of ROS leading to endothelial dysfunction is the uncoupling of endothelial nitric oxide (NO) synthase, which usually facilitates NO production (14), ultimately leading to reduce NO bioavailability. Indeed, the endothelium synthesizes the NO (15), which acts as a vasodilator, an antithrombotic, and an anti-atherosclerotic molecule (14). Endothelial nitric oxide synthase (eNOS) is the type III of NO synthases (NOS) that will lead to NO radicals synthesis from L-arginine and is expressed in endothelial cells. But in the inflammatory situation, the other NO synthases are neuronal NOS (type I) and inducible NOS (iNOS, type II). The latter will be expressed in blood vessels under pathological conditions such as inflammation or oxidative stress (16). Major cell structure and function damages will result reaction of NO with superoxide anion leading to peroxynitrite (17).

Interestingly, initial vascular injury also results in the production of ROSs species derived from NAD(P)H (18). Oxidative inflammation will ultimately cause adventitial fibrosis and smooth muscle hypertrophy (18). The latter phenomenon can also be observed in the media and intima through paracrine effects of adventitial inflammation. As a result, medial layers of vessels do not respond to NO to adapt blood flow and assure normal myocardial perfusion (19), resulting in impaired endothelium-dependent relaxation.

It is important to bear in mind that impaired myocardial perfusion and/or subsequent alteration of metabolic pathways, substrate preferences, and bioenergetics (i.e., reduced PCr/ATP ratio) might contribute to the development of several common cardiovascular diseases (20). For these reasons, perfusion and metabolic imaging are preferred methods to study early vascular and metabolic cardiotoxic effects.

### Anticancer Drugs

The vascular and metabolic cardiotoxic effects of the various anticancer drugs are given in **Table 1**.

#### Anthracyclines

Anthracyclines are a group of chemotherapy broadly used in cancer treatment, with doxorubicin (DOX) being one of the most widely used. Its cardiotoxicity is well-known with cumulative toxicity ultimately leading to permanent cardiac alteration (21). The initial alteration of this end state is thought to be at a microvascular level through ROS production (22–24), with mitochondrial superoxide production increasing with DOX dose (25).

Excessive production of ROS by DOX leads to apoptosis, cardiac function impairment, inflammation, and vascular injury (25, 26). Both the cardiomyocytes and arterial endothelial cells can experience mitochondrial dysfunction under anthracyclines (27, 28). These properties suggest that, in addition to its known direct effect on deoxyribonucleic acid through topoisomerase II beta inhibition (29), endothelial cells injury could be one

**TABLE 1 |** Myocardial vascular and metabolic effects of common anticancer drugs.

Anticancer drugs	Mechanisms of cardiotoxicity
Anthracyclines	Microcirculation alteration
	Endothelial dysfunction (NO)
	Microcirculation increased thickening
	Altered oxidative metabolism
	Impaired energetics
	ROS
	Mitochondrial dysfunction
Antimetabolites	Vasospasm
	Vasoconstriction
	Endothelial dysfunction (NO)
	Smooth cell dysfunction
	Altered oxidative metabolism
	Impaired energetics
	Mitochondrial dysfunction
RTKi	ROS
	Inhibits angiogenesis
	Endothelial dysfunction (NO)
	Vasoconstriction
	Altered oxidative metabolism
	Myocardial insulin resistance pattern
	Impaired energetics
Anti-VEGF Ab	ROS
	Mitochondrial dysfunction
	Inhibits angiogenesis
	Capillary rarefaction
	Impaired energetics
	ROS
	Mitochondrial dysfunction
Anti-HER2 Ab	Microcirculation alteration (neuregulin 1)
	Disruption of cardioprotective <i>Neuregulin-1</i> pathway
	ROS
	Mitochondrial dysfunction
ICI	Microcirculation alteration → vascular sequelae
	Dysregulated myocardial metabolism
Taxanes	Impaired energetics
	Endothelial damage
	Capillary rarefaction
Alkylating agents	Endothelial dysfunction (NO)
	ROS
	Free fatty acids accumulation
	Vasoconstriction
	Mitochondrial dysfunction

Ab, antibody; NO, nitric oxide; ROS, reactive oxygen species.

cause of anthracycline cardiotoxicity. Although anthracyclines cardiotoxicity is usually detected at a stage of altered ejection (21), studies suggest that anthracyclines cardiotoxicity occurs in

a continuum, challenging the hypothesis of irreversible cardiac injury (30, 31).

Current guidelines suggest monitoring of patients with cancer undergoing chemotherapy by echocardiography since most definitions of cardiotoxicity are based on LVEF decline (2), but the literature reports microcirculation changes long before any LVEF or contraction alterations occur (31, 32). This myocardial perfusion alteration could be the result of increased arterial walls thickening, which can occur early and even after a single DOX injection (31, 33), but is more overt with repeated injections (33). The increase in intima-media thickness under anthracyclines (34) is in part secondary to oxidative inflammation. Thus, anthracyclines cardiotoxicity appears at the histological level and these microcirculation alterations appear to be an early form of the well-known anthracyclines cardiotoxicity, suggesting modalities to assess the initial endothelial cell damage and better prevent its progression. Moreover, the combination of radiotherapy with anthracyclines potentiates heart damage. Radiotherapy has been reported as responsible for cardiac perfusion defect development, however, myocardial perfusion imaging of the combination of radiotherapy with anthracyclines remains poorly described (32).

Antimetabolites

5-Fluorouracil (5-FU) is a part of antimetabolite agents and is commonly used in the treatment of malignancies. One of the major cardiotoxicities of 5-FU is coronary vasospasm that can lead to ischemia. Its mechanism remains uncertain, with some suggesting an endothelial-dependent mechanism through endothelial dysfunction, but others an endothelium-independent with vasoconstriction of dysfunctional smooth muscle cells (35). Studies in animal models demonstrated that altered erythrocyte metabolism decreases erythrocyte ability to bring oxygen to the myocardium (36, 37). 5-FU reduces oxidative metabolism (38), impairs energetics (38), and induces mitochondrial uncoupling reducing aerobic efficiency (39). At a subcellular level, the toxicity of 5-FU and another antimetabolite drug, the capecitabine, have been shown to be mediated through oxidative stress with ROS generation leading to altered mitochondrial membrane potential in isolated rat cardiomyocytes (40).

Alkylating Agents

One of the main alkylating agents, mostly used in hematologic cancers, is cyclophosphamide, for which dose-mediated cardiotoxicity is one of the notable toxic effects. The metabolites of cyclophosphamide reported to be involved in cardiotoxicity are acrolein and 4-hydroxy-cyclophosphamide. These metabolites are involved in ROS generation (41, 42) that damage mitochondrial membrane by decreasing its detoxifying capacity, but also by disrupting normal vasotone response pathway through NO reduction or an increase in the vasoconstrictor endothelin-1 (23). In addition, cyclophosphamide is responsible for FFA accumulation and reduction of ATP production resulting in the release of proinflammatory cytokines (41). Cardiac microscopic findings of alkylating agents consist of interstitial damages, myocardial necrosis, vacuolar changes, and intramural changes in small coronary vessels (43). Similar

disturbances have also been reported with cisplatin-based chemotherapy, another alkylating agent (44).

### Taxanes

Taxanes are antimicrotubules whose main cardiotoxicity is disruption of cardiac rhythm and conduction. Heart failure (possibly in combination with DOX), ischemia, and microvascular rarefaction because of the endothelial damage might also occur (45).

### Receptor Tyrosine Kinase Inhibitors

Receptor tyrosine kinase inhibitors (RTKi) include sorafenib, pazopanib, and sunitinib. As a part of antiangiogenic therapy, RTKi inhibits the tyrosine kinase activity of the vascular endothelial growth factor (VEGF) receptor, thereby blocking the VEGF pathway, but also platelet-derived growth factor receptors and c-kit (46). Oxidative stress and dysregulation of NO signaling have been proposed to mediate RTKi-induced hypertension, as they are known to be involved in the VEGF pathway (47, 48). However, sunitinib-induced hypertension has been associated with upregulation of the endothelin peptide (49–51), a potent vasoconstrictor known to induce cardiac endothelial dysfunction (52). Experimental studies investigating the effects of VEGFR blockade on cardiac microvasculature did not reveal any changes in the number of capillaries (50, 53). Nevertheless, sunitinib induces a loss of coronary microvascular pericytes in mice (53), which might explain the impaired coronary flow reserve (CFR) of sunitinib-induced cardiotoxicity (49, 53).

Carbohydrate metabolism is altered in the myocardium of sunitinib-treated mice, which exhibits higher glucose uptake, higher gene expression of pyruvate dehydrogenase kinase, and of the pyruvate kinase isoform 2 (54), a signature of fetal myocardium in which the metabolism is mostly anaerobic. The sensor of cardiac energetic metabolism, AMP-activated protein kinase, is inhibited by sunitinib (55). Energy impairment because of the loss of mitochondrial membrane potential resulting in reduced ATP has been reported in the early stages of sunitinib-treated cardiomyocytes (56).

In a comparative study, only sorafenib among others RTKi directly impaired mitochondrial function and oxidative metabolism at clinically concentrations (57), but ROS generation was documented in several RTKi-treated myocardium (58, 59).

### Anti-vascular Endothelial Growth Factor (VEGF) Monoclonal Antibody

Another antiangiogenic approach consists of blocking VEGF with a humanized monoclonal antibody, which traps endogenous VEGF and inhibits its binding with the receptor. Bevacizumab was the first anti-VEGF antibody with a rate of systemic hypertension as high as 70%, probably because of the vascular resistance, endothelial dysfunction, and capillary rarefaction (39). Bevacizumab induces mitochondrial dysfunction plus ROS formation in isolated rat heart (60, 61) and in isolated cardiomyocytes (62).

### Anti-human Epidermal Growth Factor Receptor (HER 2)

Human epidermal growth factor receptor 2 is a receptor that promotes cell growth, proliferation, and repair in the body. Tumors can hijack these functions to proliferate. Therefore, one treatment option is to specifically target this receptor, with anti-HER2 therapy, led by Trastuzumab, which has revolutionized the treatment and prognostic of patients with HER2 positive breast cancer (63). Trastuzumab will result in ROS production, mitochondrial dysfunction, and proapoptotic signals release in cardiomyocytes (64). Unlike anthracyclines, cardiotoxicity of anti-HER2 is dose-independent and often reversible. However, it results in greater cardiotoxicity in the presence of or after anthracyclines (65).

Anti-HER2 might cause cardiomyocyte damage by disrupting the neuregulin-1 axis that normally activates protective pathways in response to stress (66), which could lead to LVEF decrease. Neuregulin-1 is a cardioactive growth factor that normally participates in the dimerization of HER receptors on cardiomyocytes to provide cell protection. However, the fact that neuregulin-1 is released from the endothelial cells in the heart leads to the question of whether the impaired LVEF is due to a direct impact of anti-HER2 on cardiomyocytes or an indirect impact *via* endothelial cells of the altered coronary microvasculature (67). Interestingly, a decrease in neuregulin-1 levels has been associated with CAD (68). The same neuregulin-1/HER pathway may also explain the increased susceptibility to anthracyclines cardiotoxicity when the two treatments are combined.

### Immune Checkpoint Inhibitors (ICIs)

Immune checkpoint inhibitors are monoclonal antibodies that restore antitumor immunity by targeting inhibitory receptors on the lymphocytes surface, such as cytotoxic T-lymphocyte-associated protein 4, programmed cell death receptor 1 (PD1), and its ligand. By reactivating the immune response against the tumor, ICIs can lead to immune-related cardiovascular adverse events that, although rare, present a case-fatality rate as high as 50% (69). The most-reported cardiac complications of ICIs are ICI-induced myocarditis but also pericardial diseases, cardiomyopathy, myocardial fibrosis, and acute heart failure (70). Microvascular damage leading to vascular sequelae has also been reported with ICI (10). Furthermore, studies are needed to explore all the different pathways involved in the cardiotoxicity of ICIs with possible yet unknown microcirculation damage. A recent *in vivo* study in mice showed that anti-PD1 drugs cause myocardial dysfunction and altered myocardial metabolism, suggesting damage at a subcellular level (71).

## IMAGING

Imaging modalities in cardio-oncology and their assessment of anticancer-drug-related cardiotoxicity are given in **Figure 1**.

### Perfusion Imaging

Perfusion imaging involves assessing the delivery of oxygen and nutrients to tissues through blood flow. It aims to describe

microvasculature that can be altered under the effect of anticancer drugs. Since 1997, Hasdai et al. reported that coronary endothelial dysfunction may be associated with myocardial perfusion defects (72). Both radiotherapy and chemotherapy have shown to be associated with microvascular dysfunction (2), although the effect of non-radiation therapies on the latter is less well-described (31). Knowing the effects of anticancer drugs on myocardial microcirculation, myocardial perfusion imaging appears to be an attractive modality to detect anticancer drug-related myocardial toxicity. Moreover, by the time cardiotoxicity-associated LV dysfunction is detectable by echocardiography, it is often too late, emphasizing the need to assess the initial microvasculature dysfunction to better prevent it.

Symptomatic oxygen supply-demand mismatch can be evaluated invasively by invasive coronary angiography (ICA), but myocardial microcirculation disturbance can occur before any visible epicardial coronary on ICA (73), requiring blood flow measurements to assess myocardial function. Myocardial malperfusion can be unmasked through fractional flow reserve (FFR), which is an invasive measurement under hyperemia to determine the significance of an epicardial coronary artery stenosis, with an  $\text{FFR} \leq 0.80$  considered to be ischemia prone (74), and defined as the ratio of maximal blood flow distal to proximal to the stenosis. The invasive measurement of CFR is intended to study the vascular bed and describe the myocardial reserve capacity for vasodilatation, and is defined as the ratio of maximal hyperemic to the resting coronary blood flow (75).

Another interesting measure to evaluate coronary microvascular dysfunction is the index of microcirculatory

resistance (IMR) (76) which is an index of coronary microvasculature and considered as abnormal if  $\geq 25$  independently of epicardial stenosis (77). However, these different parameters remain invasive, which could explain their low use in clinical practice for monitoring patients undergoing anticancer therapy, and should be discussed with respect to non-invasive techniques for the assessment of myocardial perfusion, which we review here.

### Nuclear Imaging

Nuclear imaging techniques include single-photon emission computerized tomography (SPECT) and PET. These techniques are based on the detection of radioactive gamma rays and photons (after positrons annihilation) from an injected radioactive compound, respectively.

#### Single-Photon Emission CT (SPECT)

Impairment of epicardial arteries vasodilatation, by evaluation of change in coronary diameters under pharmacological stress, has been reported after DOX infusions on CT angiography suggesting dysfunction of smooth cells and the microvascular bed (78). However, the resolution of cardiac CT is insufficient to visually assess microvessels, underlining the need for cardiac perfusion CT to assess myocardial microcirculation by detecting hypoperfused territories. Coupling of metabolic information by traditional radiotracers  $^{201}\text{Tl}$ -chloride,  $^{99\text{m}}\text{Tc}$ - sestamibi, and  $^{99\text{m}}\text{Tc}$ - tetrofosmin, is obtained by myocardial perfusion SPECT. SPECT is performed at rest and under stress, which can be achieved by exercise or pharmacologically with vasodilators (79).

The added value of SPECT is that the radiotracers will be delivered to the myocardium in proportion to flow and therefore be able to unmask a myocardial perfusion defect secondary to CAD. Territories with myocardial perfusion abnormalities may not only be secondary to CAD but reflect the myocardial cardiotoxicity at a microvascular level.

Studies have reported increased perfusion defects in DOX-treated patients with a history of radiotherapy (32, 80). Galluci et al., have suggested myocardial perfusion abnormalities, assessed by SPECT, without LVEF dysfunction in patients who had undergone chemotherapy and radiotherapy (32). However, this observational study could not strictly conclude that the findings were only due to the chemotherapy because of the lack of a control group before cancer treatment, and because of the inclusion of patients with a history of radiotherapy.

Some studies described LVEF dysfunction after the introduction of DOX in patients with cancer (81), but there are very little data on the incidence of SPECT perfusion defect in patients under DOX alone. One study on 36 patients with breast carcinoma evaluated before and after anthracyclines found no significant perfusion defect after anthracyclines (34), leaving the question of myocardial perfusion monitoring with  $^{99m}\text{Tc}$ -sestamibi SPECT subject open to debate.

### Positron Emission Tomography

Compared with SPECT, PET allows assessment of myocardial blood flow with better spatial resolution and sensitivity. CFR can be quantified as the ratio of myocardial blood flow between stress and rest on PET (82). The most commonly used and validated radionuclide for cardiac perfusion evaluation is rubidium-82 ( $^{82}\text{Rb}$ ) (82). Although  $^{82}\text{Rb}$  PET is often used for semiquantitative myocardial perfusion, it may assess coronary microvascular function by absolute quantification of myocardial perfusion and myocardial perfusion (or flow) reserve (MPR) (83). MPR is the ratio of stress flow to resting flow and describes the capacity of the coronary bed to maximize flow (84).

Myocardial perfusion reserve has been reported to be decreased after DOX exposure, representing a possible early marker of DOX myocardial cardiotoxicity (85). Detection of changes in mitochondrial function, estimation of myocardial blood flow and myocardial oxygen consumption, and thus, the ability of coronary arteries to respond to stress, can also be assessed by  $^{11}\text{C}$ -acetate rest stress PET. Using the latter, a decrease in myocardial perfusion and oxygen consumption reserve in DOX-treated rats compared with the control animals has been reported (86).  $^{11}\text{C}$ -acetate PET is not only used to investigate DOX cardiotoxicity but has also been evaluated in sunitinib-induced cardiotoxicity. Similarly, an *in vivo* study in rats described a decrease in myocardial perfusion, evaluated by  $^{11}\text{C}$ -acetate PET, as early as 5 days after treatment initiation (87).

### Cardiac MR

Common practices remain the assessment of cardiotoxicity by echocardiography because of its ability and availability to detect LVEF alteration, which is the current standard for oncologic treatment cardiotoxicity (88). However, the gold standard in

LVEF evaluation remains CMR imaging (89). But in addition to LVEF assessment, it is currently admitted that CMR with vasodilator stress perfusion should be performed to non-invasively investigate microvascular dysfunction (90). Yet, we know that anthracyclines may be responsible for myocardial damage at a histologic level long before any overt LVEF decrease (91). Although most studies of anthracyclines have focused on their effect on myocyte damages (92), more recent studies suggest that DOX cardiotoxicity may present as direct vascular injury and arterial damage with coronary arteriolar wall abnormalities (31, 33, 93, 94). Some mechanisms of microcirculation damage arise from increased thickening of microcirculatory arterioles and loss of smooth muscle cells, which may contribute to myocardial perfusion defects.

Thus, the literature reports that DOX cardiotoxicity results in microvascular dysfunction, and we know that microvascular can technically be assessed by myocardial perfusion on CMR. We had to wait until 2021 to finally find a study that proved *in vivo* that there was a reduction in myocardial perfusion well before any overt LVEF alteration. Indeed, to the best of our knowledge, Galán-Arriola et al. (31) were the first to describe in large animals the impact of DOX on coronary microcirculation, assessed by CMR but also by invasive measurement and histology, under different DOX protocols. In this study, the alteration of myocardial perfusion by CMR followed a similar pattern to that observed in the assessment of microcirculatory function by CFR. Indeed, they showed that in the early stages of DOX treatment, there was a decline in CMR perfusion. This decline in perfusion was present although LVEF, cardiac motion, cardiac contractility were not impaired; and was persistent as long-term changes with cumulative doses of DOX.

Myocardial perfusion assessment by CMR is a validated non-invasive assessment of microvascular CAD (95) and has been shown to outperform SPECT in detecting obstructive CAD (96–99). Newer CMR techniques that could quantitatively detect epicardial and microvascular CAD have correlated well with IMR and FFR measurements (77), and coronary sinus flow evaluation could be a good surrogate for CFR measurements (100). Although to the best of our knowledge, no study has yet reported myocardial perfusion CMR findings of anthracyclines-treated patients, it is legitimate to speculate that vasoconstriction and increased wall thickness of the heart microvasculature may reveal a myocardial perfusion defect and decreased myocardial blood flow reserve. Myocardial perfusion is acquired during the first pass of gadolinium-based contrast agents, based on an ECG-triggered fast T1-sensitive pulse sequences that can be acquired both at rest and with stress. The additional benefit of stress in CMR perfusion compared with resting perfusion alone is still debated but is theoretically used to unmask myocardial perfusion defect that could be compensated at rest (101). Indeed, stress could reveal insufficient coronary reserve resulting in decreased perfusion and ischemia in territories with thickened vessels walls and impaired ability to respond to stress-induced vasodilation. Although the mechanisms leading to 5-FU-related cardiotoxicity are numerous and detailed elsewhere (102), ischemia, especially secondary to vasospasm, can be imaged by perfusion defect in the coronary territory of the vasospasm (103, 104).

Regarding the evaluation of anti-VEGF myocardial cardiotoxicity with perfusion CMR, there are very sparse data in the literature. A small study on 9 patients evaluated both resting and stress perfusion with CMR before treatment and at 4 and 6 weeks of treatment (105). They were able to show a decrease in myocardial blood flow on resting perfusion after treatment introduction but no difference under stress, and an increase in vascular permeability. These preliminary findings suggest that anti-VEGF cardiotoxicity leads to microvascular constriction, which may, fortunately, be reversible, and that microvascular endothelial dysfunction may be responsible in part for impaired LVEF.

## Metabolic Imaging

Metabolic imaging focuses and targets changes in metabolic pathways and energetics. It includes CMRS and nuclear imaging techniques such as SPECT and PET.

### Cardiac Magnetic Resonance Spectroscopy

Cardiac magnetic resonance spectroscopy has several advantages for metabolic imaging since it is able of measuring several metabolic biomarkers without using ionizing radiation (106). Metabolites containing proton ( $^1\text{H}$ ) such as creatine or lipids; containing carbon ( $^{13}\text{C}$ ) such as glucose, and containing phosphorus ( $^{31}\text{P}$ ) such as PCr or ATP can be assessed by CMRS. In addition, the development of  $^{31}\text{P}$  saturation magnetic resonance spectroscopy allows the measurement of the metabolic rate of ATP production *via* the enzyme creatine kinase (= CK flux) (106, 107).

Early studies performed on isolated animal hearts have demonstrated several alterations in the cardiac metabolic. The injection of [ $1\text{-}^{13}\text{C}$ ]glucose into isolated perfused hearts treated for 10 weeks with anthracyclines highlighted altered glycolytic metabolism (108). Similarly, abnormal cardiac bioenergetics, as revealed by a reduced PCr/ATP ratio, was measured with  $^{31}\text{P}$ -CMRS in an isolated animal hearts of acute (109) and chronic (110–112) anthracycline-related cardiotoxicity. In addition, Bittner et al. showed that hearts chronically exposed to DOX failed to adapt metabolically, as evidenced by the delayed recovery of PCr after hemodynamic stress (113). Recently, Henderson et al. showed that acute and clinically relevant exposure to DOX in isolated, perfused rat hearts induced a reduction in energy reserve, as measured by a decrease in PCr, in response to the cardiac-stimulant isoproterenol (114). These studies demonstrated abnormal cardiac energetics production and utilization, even in the setting of acute anthracycline exposure. Interestingly, the myocardial PCr/ATP ratio was reduced after 6 weeks of anthracycline treatment without evidence of cardiac damage in an *in vivo* study (110). In addition, the authors showed a strong correlation between cardiac energetics and LV systolic and diastolic dysfunction after 8 and 10 weeks of treatment. The same group then demonstrated that the absolute concentration of PCr was decreased in DOX-treated mice and that  $^{31}\text{P}$ -CMRS also detected a reduced rate of ATP synthesis through CK reaction (115). Importantly, overexpression of cardiac-specific myofibrillar isoform of CK restored impaired PCr and CK flux, which was associated

with improved LVEF and survival in DOX-treated mice (115), opening up a new possibility for preventive therapy.

Recent research has focused on improving the signal-to-noise ratio of conventional CMRS, with the development of hyperpolarization CMRS: the injection of hyperpolarized [ $1\text{-}^{13}\text{C}$ ]pyruvate and [ $2\text{-}^{13}\text{C}$ ]pyruvate enables measurement of the flux through the pyruvate dehydrogenase (PDH) complex and TCA flux, respectively (116). A decrease in PDH flux, representative of reduced oxidative mitochondrial carbohydrate metabolism, was observed in the myocardium of DOX-treated rats for 3 weeks without impairment of cardiac function (117). After 6 weeks of treatment, the authors showed, in addition to reduced PDH activity, a decrease of TCA cycle flux and impaired cardiac function. This altered carbohydrate metabolism reflected the loss of mitochondrial integrity, which was not because of the oxidative stress in this study, and preceded cardiac function impairment.

The exploration of cardiac energetics in the clinic has been recently proposed. The authors found no difference in cardiac PCr/ATP ratio of anthracycline-treated women despite a 5% reduction in LVEF between the start and end treatment (118). This could be explained, at least in part, by the small number of patients in whom CMRS was possible (11 patients).

### Nuclear Imaging

Several radiopharmaceuticals can be used as biomarkers of myocardial metabolism using nuclear imaging, the two best known being iodine-123 betamethyl-iodophenyl-pentadecanoic acid (BMIPP) for the assessment of myocardial FFA uptake and 2'-deoxy-2'-[ $^{18}\text{F}$ ]fluoro-D-glucose (FDG) for the assessment of cardiac glucose uptake. Because myocardial metabolism is tightly regulated, the heart switches from FFA metabolism to glycolysis in high-insulin/glucose levels and low oxygen by increasing its glucose transporter protein translocation to the plasma membrane (119). Hence, PET with FDG under fasting condition is preferred for oncology study (minimize myocardial uptake) but is performed under fasted condition or with glucose load after an overnight fasting for cardiac study (maximize myocardial uptake).

Early studies conducted two decades ago showed a significantly lower myocardial BMIPP uptake in patients treated with DOX (120) and taxanes (121), but other studies showed that only one in four (122), and one in six (123) patients displayed hypomyocardial BMIPP accumulation. Importantly, modeling of kinetics, which was measured by the acquisition of dynamic time sequences in the latter study, revealed a significant decrease in BMIPP flux in DOX-treated patients (123). This analysis more accurately reflects the features of fatty acid metabolism disorders by measuring the metabolic flux of the tracer rather than its accumulation in the myocardium. The lower cardiac uptake of BMIPP, which is a biomarker of impaired fatty acid beta-oxidation, was predictive of LV dysfunction (120).

An exciting exploration in cardio-oncology is ketone body imaging. This has been proposed with cardiac  $^{11}\text{C}$ -acetoacetate PET. As a ketone body, acetoacetate can be used as a substrate by the heart and be involved in cardioprotection through its antioxidant activity plus mitochondrial membrane repair

(124, 125). Greater uptake and retention of  $^{11}\text{C}$ -acetoacetate in the myocardium was found in non-fasted rats treated for 6 weeks with DOX, which may be associated with mitochondrial membrane alteration (126). Although it has been studied only once in this field, ketone body imaging may hold promise as a theranostic approach.

In 2012, Borde et al. first described enhanced  $^{18}\text{F}$ -FDG uptake in the myocardium of DOX-treated patients, highlighting the ability of PET to early detect cardiotoxicity (127). Similar observations have been reproduced by others attempting to better understand the increased myocardial  $^{18}\text{F}$ -FDG uptake in animals and patients treated with chemotherapy. First, DOX dose-dependently increased myocardial metabolic flux of  $^{18}\text{F}$ -FDG measured by dynamic PET in the fasted mice (128). The same group demonstrated that a low pretreatment  $^{18}\text{F}$ -FDG standardized uptake value (SUV) in Hodgkin's disease patients may predict the development of chemotherapy-induced cardiotoxicity, which was subsequently detected by a higher myocardial  $^{18}\text{F}$ -FDG SUV (128). Another study showed that 12% of 121 patients with breast cancer treated with anthracycline or trastuzumab had increased  $^{18}\text{F}$ -FDG uptake in the right ventricle, which was significantly associated with cardiotoxicity (129). Second, increased LV  $^{18}\text{F}$ -FDG uptake correlated with LVEF decline after two cycles and at the end of DOX therapy in a retrospective study including a cohort of 43 patients (130). Another interesting study explored  $^{18}\text{F}$ -FDG myocardial uptake and myocardial perfusion (through  $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT) in a retrospective cohort of 332 patients followed for malignant disorders (131). As part of an oncologic PET protocol, patients were fasted to avoid myocardial  $^{18}\text{F}$ -FDG uptake: 36% of patients had no  $^{18}\text{F}$ -FDG uptake, 22.5% had diffuse  $^{18}\text{F}$ -FDG uptake, 8% had focal  $^{18}\text{F}$ -FDG uptake, and 30.5% had a focal uptake overlying the diffuse pattern  $^{18}\text{F}$ -FDG uptake. Among all the patients, multivariate logistic regression identified focal myocardial  $^{18}\text{F}$ -FDG uptake as a predictor of impaired LVEF and myocardial perfusion (131). It is important to bear in mind two interesting points. First, no direct mechanisms that could explain the increased cardiac  $^{18}\text{F}$ -FDG uptake have been explored in these reports. This could be because of the recruitment of inflammatory cells, switch to anaerobic glycolysis, or being associated with other pathological mechanisms. Second, the correlation between  $^{18}\text{F}$ -FDG uptake and LV function was made at the same time, which cannot directly prove the ability of early detection of cardiotoxicity before the decline of LV function. In terms of mechanisms and correlations, the increase in cardiac uptake of  $^{18}\text{F}$ -FDG seven days after DOX treatment in mice was directly correlated with oxidative stress and antioxidant mechanisms assessed by biochemical measurements (132). This is particularly interesting knowing the close relationship between metabolic imbalance (i.e., mismatch of oxidative metabolism plus reduced ATP production) and ROS generation in mitochondria (133, 134).

Chemotherapy-induced cardiotoxicity is not limited to an increase in  $^{18}\text{F}$ -FDG uptake. The SUV of  $^{18}\text{F}$ -FDG was significantly reduced in the fasted rats treated for 6 weeks (135) and in non-fasted rats treated for 4 weeks (136) with DOX.  $^{18}\text{F}$ -FDG PET could have detected a loss of cell viability and

necrosis in these experimental models, which was associated with decreased LVEF (136). This supports the fact that dietary status is important in the cardiac  $^{18}\text{F}$ -FDG PET investigation.

With respect to antiangiogenic therapies, few reports have described the role of  $^{18}\text{F}$ -FDG PET. In 2011, a case report described decreased myocardial  $^{18}\text{F}$ -FDG uptake in patients treated with imatinib plus sorafenib who later developed a cardiac event (137). Later, O'Farrell et al. also showed an increase in  $^{18}\text{F}$ -FDG uptake 2–3 days after the introduction of sunitinib in mice and 5 days in rats (87). In another study, sunitinib induced higher  $^{18}\text{F}$ -FDG uptake after 1 week of treatment in fasted mice but not in non-fasted mice (138), highlighting once again a role of the dietary status on myocardial  $^{18}\text{F}$ -FDG uptake for further investigations. In both studies, this early side effect was associated with a switch from oxidative metabolism to glycolytic metabolism (138) and correlated with late myocardial hypertrophy measured after 6 weeks of treatment (139). Moreover, the metabolic flux of  $^{18}\text{F}$ -FDG from the blood to the cytoplasmatic glycolysis, measured by dynamic time sequence acquisition and kinetic modeling, was reduced after 3 weeks of treatment (87, 138) with sunitinib and was associated with an insulin resistance pattern (138).

## Mitochondrial Function Imaging

*In-vivo* assessment of cardiotoxicity-induced ROS production is tempting as there is a close relationship between altered circulation, metabolism, and oxidative stress.  $^{18}\text{F}$ -labeled analog of dihydroethidium ( $^{18}\text{F}$ -DHMT) is a radioactive compound that can assess free radicals because it is trapped in the cell when oxidized by ROS (140, 141). In an initial *in-vivo* study in mice, the authors reported a 2-fold increase in cardiac retention of  $^{18}\text{F}$ -DHMT after a single injection of DOX, which revealed ROS production compared with controls (141). This observation was later confirmed with an increased cardiac uptake of  $^{18}\text{F}$ -DHMT in DOX-treated rats following 4 and 6 weeks of treatment (142). Interestingly, no impairment of cardiac function was found after 4 weeks of treatment, but 6 weeks of DOX treatment induced a decrease in LVEF (142). In another study, dynamic time sequence  $^{18}\text{F}$ -DHMT PET and kinetic modeling confirmed higher absolute quantification of myocardial ROS production in beagle dogs following 2 weeks of DOX treatment (143).

Similarly, new radiopharmaceuticals have been developed to assess early DOX myocardial cardiotoxicity detection, such as  $^{18}\text{F}$ -labeled lipophilic cation PET tracers (144). Its principle is to image mitochondrial damage by  $^{18}\text{F}$ -labeled lipophilic tracers, which diffuse across mitochondrial membranes depending upon the mitochondrial membrane potential (144). The tracers will therefore accumulate in cardiac tissue in case of mitochondrial damage, which is one of the possible mechanisms of myocardial cardiotoxicity of DOX, allowing early detection of its cardiotoxicity.

In SPECT imaging, in the same perspective, the usual  $^{99\text{m}}\text{Tc}$ -sestamibi, which is used to assess myocardial perfusion, is also a lipophilic cation and so its myocardial distribution depends on the mitochondrial membrane potential additionally to regional myocardial perfusion. Safee et al. recently demonstrated in a rat model a correction tool to free the  $^{99\text{m}}\text{Tc}$ -sestamibi from its

**TABLE 2 |** This table summarizes early perfusion, metabolic and mitochondrial function imaging findings suggestive of DOX myocardial toxicity that subsequently revealed impaired left ventricle ejection fraction.

Reference	Early myocardial toxicity with no overt cardiac dysfunction	Late cardiac dysfunction	Species
Saito et al. (120)	Reduced $^{123}\text{I}$ -BMIPP [2 to 3 weeks]	Decreased LVEF [variable]	Human

[time] = from the beginning of treatment to the assessment of alteration on imaging.

CFR, coronary flow reserve; CMR, cardiac MRI;  $^{18}\text{F}$ -DHMT,  $^{18}\text{F}$ -labeled analog of dihydroethidium; DOX, doxorubicin;  $^{18}\text{F}$ -FDG,  $^{18}\text{F}$ -Fluoro-D-glucose;  $^{123}\text{I}$ -BMIPP,  $^{123}\text{I}$ -Betamethyl-iodophenyl-pentadecanoic acid; LVEF, left ventricle ejection fraction; PCr, phosphocreatine; PDH, pyruvate dehydrogenase.

perfusion imaging, to assess only the mitochondrial potential, and thus, its possible perturbation by anthracyclines (145). They proposed to correct the  $^{99\text{m}}\text{Tc}$ -sestamibi with a lipophilic uncharged radiotracer that would thus be a perfusion tracer independent of the mitochondrial membrane potential [the bis (N-ethoxy-N-ethylthiocarbamate)nitrido  $^{99\text{m}}\text{Tc}(\text{V})$ ]. The latter  $^{99\text{m}}\text{Tc}$ -NOET would, therefore, be able to detect DOX cardiotoxicity through its mitochondrial damage.

## PERSPECTIVES

We are convinced that the assessment of the mechanisms of anticancer drug cardiotoxicity by imaging is a cornerstone in the new era of cardio-oncology. **Table 2** supports our assertion by summarizing studies that demonstrate DOX-induced cardiotoxicity early before overt LVEF impairment (**Table 2**).

## Imaging Opportunities

We have seen throughout this review that most studies have been conducted in animal models. We are confident that this research has been and will be of great importance for the development of a standardized protocol to predict drug-related cardiotoxicity and to test preventive interventions.

Early detection of metabolism and vascular alteration is paramount to prevent DOX-induced permanent cardiac dysfunction (**Table 2**) and could be extended to other anticancer drugs since several vascular and metabolic cardiotoxic effects have been described in this review (**Table 1**). The assessment of myocardial cardiotoxicity by CMR seems to be of interest,

to seek other complications of oncologic therapies such as ICI-induced cardiotoxicity. The major cardiotoxicity reported in this therapeutic class is myocarditis, with CMR being of great importance when suspected (146). Although not a commonly used modality for myocardial inflammation (147), increased  $^{18}\text{F}$ -FDG uptake on PET could be found in myocarditis, including in ICI myocarditis (148). Interestingly,  $^{18}\text{F}$ -FDG uptake has also been reported as a marker of anthracyclines cardiotoxicity, either *via* inflammatory response or altered myocardial metabolism (149). Fusion between  $^{18}\text{F}$ -FDG and CMR have also been reported (148) for simultaneous vascular, metabolic, and functional imaging and may benefit from creatine measurement with proton CMRS (150) since creatine is decreased in both ischemic (151) and non-ischemic (152) cardiovascular disease.

## Clinical Feasibilities

Because most studies of perfusion and metabolic imaging have been performed in animal models, their clinical relevance in routine practice is questionable. Anyhow, further clinical studies are required to ensure the utility of early detection of anticancer drugs.

Cardiac magnetic resonance imaging appears to be a non-invasive, radiation-free tool for monitoring patients with cancer, capable of imaging microcirculation, metabolism, and myocardial inflammation, which could be offered routinely before and after the introduction of an anticancer drug. We believe that CMR could be a justifiable perfusion approach as a part of standard patient care. Indeed, we have seen that altered myocardial perfusion in large animal models has been

reported by resting myocardial perfusion on CMR (31). Multiple other CMR parameters have been reported to be related to cardiotoxicity of anticancer drugs (153–156), so the addition of a rapid perfusion sequence to the CMR protocol would be sufficient to obtain an argument for cardiotoxic effect. As the gold standard, CMR would also provide an accurate evaluation of LVEF. Unfortunately, LVEF assessment is so far performed in daily practice by echocardiography because of the lack of access to CMR. This would be the only limitation we see for its routine integration into the health care of patients with cancer.

We believe that the use of nuclear perfusion imaging in daily practice is difficult to justify. One of the main possible obstacles is the use of radiation and the cost of the technique that would allow assessment of myocardial perfusion without assessing oncologic follow-up. Nevertheless, it may be interesting to consider the integration of  $^{18}\text{F}$ -FDG PET in the follow-up of patients with cancer in order to assess tumor progression and, at the same time, to look for possible cardiotoxic effects. Indeed, the most PET scans for oncology monitoring use  $^{18}\text{F}$ -FDG, which is also, as mentioned earlier, sensitive to myocardial metabolic imbalance and also to myocardial inflammation. This capability of PET for whole-body imaging would be attractive in patients with cancer to concomitantly allow imaging of tumor progression in addition to an assessment of myocardial toxicity, thus providing a unique modality. We believe that further studies regarding the place of PET imaging in the future of cardio-oncology are required.

## CONCLUSION

Early detection of cardiotoxicity is crucial and offers the opportunity for early therapeutic intervention. In this review, we have shown that perfusion imaging, metabolic imaging, and mitochondrial function imaging are capable of assessing myocardial cardiotoxic effects of cancer therapeutics before irreversible cardiac damage occurs (**Figure 1, Table 2**). Knowledge of these possible early imaging findings in anticancer drug-related myocardial toxicity could change the paradigm of “late-onset cardiotoxicity.” Earlier detection would allow for better prevention, with specific therapeutics attempting in part to reduce oxidative stress. Current guidelines on cardiotoxicity do not include myocardial and metabolic perfusion imaging, but in light of this review, it may be worthwhile to add these parameters to better detect and prevent dramatic progression.

## AUTHOR CONTRIBUTIONS

FC and JS contributed equally to this study and wrote the manuscript. FT did proofreading and provided useful advice. All authors contributed to the article and approved the submitted version.

## FUNDING

This study was performed by a laboratory member of the France Life Imaging Network (grant ANR-11-INBS-0006).

**Background and Aims:** With the increasing coexistence of cardiovascular disease and cancer in contemporary clinical practice, studies on the outcomes in acute myocardial infarction (AMI) patients with cancer has not been systematically investigated. This study sought to investigate the effect of coexisting cancer on the treatment and clinical outcomes among AMI patients.

**Methods:** We retrospectively integrated and analyzed cardiovascular data of 6,607 AMI patients between June 2016 and December 2019. Patients with cancer were compared with pair-matched cancer-naïve patients. Cox proportional hazards models were constructed to compare the differences in outcomes.

**Results:** Of 6,607 patients, 2.3% ( $n = 150$ ) had been diagnosed with cancer. Patients with cancer were older ( $70.3 \pm 10.0$  vs.  $63.9 \pm 11.5$  years,  $P < 0.001$ ) and had a higher burden of comorbidities. Moreover, patients with cancer tended to receive clopidogrel (52.0 vs. 40.0%,  $P = 0.004$ ) rather than ticagrelor (45.6 vs. 58.2%,  $P = 0.003$ ) than those without cancer. After pairwise matching, patients with cancer were less likely to undergo in-hospital percutaneous coronary intervention (61.3 vs. 70.0%,  $P = 0.055$ ). And after 3-year follow-up, the cumulative incidence of cardiovascular death (14.0 vs. 8.3%; adjusted HR, 1.93; 95% CI, 1.11–3.39;  $P = 0.021$ ) among patients with cancer was significantly higher than that among the matched controls, a similar pattern was observed for the composite outcome of cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke (16.0 vs. 10.3%; adjusted HR, 1.98; 95% CI, 1.21–3.26;  $P = 0.007$ ). Moreover, patients with a historical cancer diagnosis within 5 years had a higher risk of cardiovascular ischemic events.

**Conclusions:** AMI patients with a concomitant diagnosis of cancer tended to be treated with conservative therapies and were at substantially higher risk for adverse cardiovascular outcomes.

**Keywords:** cancer, acute myocardial infarction, cardiovascular outcomes, percutaneous coronary intervention, conservative therapies

## INTRODUCTION

Cancer and cardiovascular disease are the leading causes of disease-related death worldwide, together accounting for nearly 70% (1). Due to earlier detection and modern treatment regimens, cancer-related mortality has decreased significantly (2), and two-thirds of patients with cancer can survive at least 5 years with the disease (3). Likewise, there has been a global decline in deaths from acute myocardial infarction (AMI) (4). Although cancer and cardiovascular disease are regarded as two distinct disease processes, there is a considerable overlap of risk factors for these diseases, such as advanced age, diabetes (5), smoking (6), and obesity (7). As life expectancy increases, non-cancer-related mortality from cardiovascular disease has become more important during cancer survivorship (8, 9), and cardiovascular disease has been shown to be the leading cause of death in cancer patients (10, 11).

When cancer patients present with AMI, their management poses unique challenges for clinicians. Many old and new emerging anti-cancer agents are associated with cardiovascular toxicities (12, 13). The lasting cardiovascular side effects of cancer treatments means that the compensatory reserve for acute clinical events such as AMI may also be reduced (14). At a cumulative (i.e., lifetime) dose of 400–450 mg/m<sup>2</sup> doxorubicin, a 10% rate of heart failure can be expected among patients aged over 65 years (15). In addition, cancer is commonly associated with hematologic and coagulation abnormalities (16), which poses a major obstacle to percutaneous coronary intervention (PCI) and the use of antithrombotic agents. Unfortunately, patients with cancer are commonly excluded from randomized controlled trials exploring best practices for the treatment of AMI, leading to a scarcity of reliable data on clinical outcomes in this cohort to guide clinical decision-making, which compounds the dilemma faced by clinicians.

Therefore, in this retrospective cohort study, we analyzed the clinical characteristics, treatment patterns, and outcomes in AMI patients with cancer and sought to define the influence of cancer duration and treatment pattern on the cardiovascular outcomes.

## MATERIALS AND METHODS

### Study Design and Patient Population

A retrospective, single-center study was performed at the Second Affiliated Hospital of Harbin Medical University, which was approved by the ethics committee of Harbin Medical University. The study procedures were conducted in compliance with the principles of the Declaration of Helsinki, and patient information was collected anonymously. All AMI patients from June 2016 to December 2019 were included in the study. Myocardial infarction (MI) was defined according to the fourth universal definition of MI (17). The population included in the final analysis consisted of 6,607 AMI patients. All detailed clinical data of those patients were collected from electronic medical records, including age, sex, type of malignancy, cardiovascular risk factors [smoking status, hypertension, hyperlipidemia, diabetes mellitus, and previous coronary heart disease (CHD)], treatment, and outcomes. During a 3-year follow-up period, patients were

surveyed semi-annually *via* telephone about major adverse events using a standardized questionnaire.

### Outcomes

Our primary outcome was defined as cardiovascular mortality during follow-up. Secondary outcomes included all-cause mortality, major adverse cardiovascular and cerebrovascular events (MACCE), non-fatal MI, non-fatal stroke, and revascularization. MACCE is composed of cardiovascular death, non-fatal myocardial infarction, or non-fatal stroke.

### Statistical Analysis

For all statistical tests, a two-tailed *P*-value < 0.05 indicated statistical significance, and data analyses were performed using R version 3.6.2 software (R Institute Inc.). Continuous variables are presented as the means  $\pm$  standard deviations (SDs) if normally distributed or presented as medians with interquartile ranges (IQRs) if non-normally distributed. Discrete variables are presented as frequencies (percentages), and missing data were excluded from the summary statistic calculations. To evaluate the differences in baseline characteristics between unmatched groups, Student's *t*-test was used for nearly normally distributed continuous variables, the Wilcoxon rank-sum test was used for non-normally distributed continuous and ordinal discrete variables, and Categorical data have been compared using the  $\chi^2$  or Fisher's exact test. Furthermore, to make the two groups comparable with regard to the vast majority of baseline characteristics, pairwise matching was performed *via* a greedy matching algorithm to match each pair of reference patients and patients with cancer according to the following restrictions: (1) age within 1 year, (2) sex, (3) hyperlipidemia status, (4) smoking status, and (5) diabetes status. The control group allowed a variable number of reference matches and a maximum of 4 matches per patient with cancer. Except for unpaired patients, each patient pair was used once in the further analyses. Comparisons between reference patients and patients with cancer were tested *via* the same test for baseline characteristics and outcomes. To evaluate the incremental relative risk increase among subgroups in the heterogeneity analysis, models were fit with an indicator for any history of cancer and with another indicator for the subgroup. Forest plots were drawn to analyze the heterogeneity of the effect of coexisting cancer on the event risk between subgroups.

## RESULTS

### Patient Characteristics

A total of 6,607 AMI patients were included between June 2016 and December 2019. Among those patients, 150 (2.3%) had been diagnosed with cancer. According to the order of frequencies, the most prevalent malignancies were lung (31, 20.7%), colorectum (21, 14.0%), stomach (19, 12.7%), and breast (15, 10.0%) cancers (**Supplementary Table S1**).

The characteristics of the overall cohort and matched cohort are summarized in **Table 1**. Before matching, the group of patients with cancer was older ( $70.3 \pm 10.0$  vs.  $63.9 \pm 11.5$  years, *P* < 0.001) and had higher proportions of patients with

matching with the exception of higher proportions of patients with previous CHD (44.9 vs. 26.8%,  $P < 0.001$ ), previous MI (21.8 vs. 11.1%,  $P = 0.001$ ) and previous PCI (16.3 vs. 5.9%,  $P < 0.001$ ) in the group of patients with cancer than in the matched controls. Moreover, patients with cancer were less likely to undergo in-hospital PCI (61.3 vs. 70.0%,  $P = 0.055$ ).

## Outcomes in the Cancer and Matched Non-cancer Groups

With regard to the long-term outcomes, patients with cancer had a significantly higher cumulative incidence of all-cause mortality (22.7 vs. 9.8%; adjusted HR, 2.40; 95% CI, 1.52–3.79;  $P < 0.001$ ) (**Supplementary Figure S1**) and cardiovascular mortality (14.0 vs. 8.3%; adjusted HR, 1.934; 95% CI, 1.11–3.39;  $P = 0.021$ ) (**Figure 1; Supplementary Table S2**). MACCE were also significantly higher in the patients with cancer than in the matched non-cancer group (16.0 vs. 10.3%; adjusted HR, 1.98; 95% CI, 1.21–3.26;  $P = 0.007$ ). Moreover, there was no significant difference in MI (2.7 vs. 1.7%; adjusted

HR, 1.64; 95% CI, 0.50–5.41;  $P = 0.419$ ), stroke (0.7 vs. 0.9%; adjusted HR, 0.84; 95% CI, 0.10–7.34;  $P = 0.876$ ), and revascularization (1.3 vs. 4.6%; adjusted HR, 0.259; 95% CI, 0.061–1.097;  $P = 0.067$ ) between patients with or without cancer. Cardiovascular mortality tended to be similar across all pre-specified subgroups (**Figure 2**), as was all-cause mortality and MACCE (**Supplementary Figures S2, S3**).

Among 150 patients with cancer, 52 had a historical cancer diagnosis beyond 5 years before AMI, 59 had a historical cancer diagnosis within 5 years before AMI, and the other 39 had a current cancer diagnosis after AMI. The incidences of all-cause mortality, cardiovascular mortality and MACCE were significantly higher among patients with a historical cancer diagnosis within 5 years than among those without cancer (adjusted HR, 3.38; 95% CI, 1.88–6.04;  $P < 0.001$ ; adjusted HR, 2.59; 95% CI, 1.25–5.35;  $P = 0.010$ ; and adjusted HR, 2.66; 95% CI, 1.39–5.11;  $P = 0.003$ , respectively) (**Table 2**). A similar pattern was observed for all-cause mortality among patients with a current cancer diagnosis (adjusted HR, 2.71; 95% CI, 1.25–5.88;  $P = 0.012$ ).

<sup>a</sup>HRs were calculated using adjustments for history of coronary heart disease, history of myocardial infarction, history of percutaneous coronary intervention and history of chronic kidney disease.

## DISCUSSION

The main findings of this study are as follows: (a) among AMI patients, those with cancer were generally older and more often presented with comorbidities than those without cancer; (b) patients with cancer tended to be treated with conservative medical strategies with a weaker P2Y12 inhibitor in dual antiplatelet therapy (DAPT) and less PCI; (c) patients with cancer had a significantly higher incidence of cardiovascular mortality and MACCE; (d) patients with a historical cancer diagnosis within 5 years had a higher risk of cardiovascular ischemic events.

### Patients With Cancer Tended to Be Treated With Less PCI

We found that patients with cancer are less likely to undergo PCI treatment during hospitalization than those without cancer, and they were also less likely to undergo revascularization during follow-up. According to previous data, patients with active cancer have ~2- and 3-fold higher risks of 90 days for readmission with AMI or major bleeding after PCI, respectively, than patients without cancer (18). Thus, clinicians are often wary of performing invasive therapies in patients with cancer. However, data from large retrospective studies showed that PCI results in significantly lower risks of in-hospital all-cause mortality and MACCE than conservative treatment, irrespective of whether the patient had a cancer diagnosis, and PCI did not increase the risk of in-hospital complications, including massive bleeding and stroke (19). To date, there has been no large randomized trial to assess the benefits and risks of invasive and conservative approaches to treating AMI in patients with cancer, and such patients are often excluded from clinical trials. The current guidelines recommend that

percutaneous revascularization should be considered even in cancer patients with an expected survival duration of <1 year (20). Balloon angioplasty without stents are recommended to limit the duration of antiplatelet therapy. If stents need to be used, those with fast reendothelialization rates may be a better choice.

### Clinicians Prefer Conservative Clopidogrel Rather Than Ticagrelor for Aspirin-Based DAPT

The coexistence of high risks of ischemia and major bleeding presents a challenge for clinicians when treating AMI patients with cancer with regard to antiplatelet therapy. When faced with this dilemma, clinicians prefer conservative approaches with regard to aspirin-based DAPT. A less potent P2Y12 inhibitor, namely, clopidogrel rather than ticagrelor, was administered to AMI patients with cancer, but there is a lack of reliable evidence to confirm the greater benefits of clopidogrel among such high-risk patients.

### Patients With Cancer Had a Significantly Higher Incidence of Adverse Cardiovascular Outcomes Than Those Without Cancer

A previous study that included 6,563,255 AMI patients revealed that patients with cancer, irrespective of the cancer type, had higher risks of in-hospital mortality, MACCE, and stroke than those without cancer (21). Inflammation plays a vital role in the progression of both cancer and atherosclerotic lesions (including CHD) (22). Although the mechanism underlying this association is unclear, we propose that local malignancies might increase vascular wall inflammation by releasing inflammatory cytokines

and that this circulatory inflammation might subsequently lead to progressive coronary atherosclerosis. In addition, cardiotoxicity can be a major complication of cancer treatment, radiotherapy is recognized as a cardiovascular risk factor among patients with cancer, and many anticancer drugs (anthracyclines, vinca alkaloid anti-metabolites, and biologics) are known to be closely associated with acute early and late cardiovascular adverse events. Perhaps because of the overlap of common risk factors for cancer and CHD and the susceptibility to atherosclerosis caused by oncology treatments (such as radiation therapy or tyrosine kinase inhibitors), patients with cancer tend to exhibit a relatively higher cardiovascular risk. In particular, there was no significant difference in cardiovascular mortality and MACCE for 1 year, but we found that there was no significant difference in cardiovascular mortality and MACCE for 1 year (**Supplementary Table S3**), and the 3-year incidences of all-cause mortality, cardiovascular mortality and MACCE were significantly higher among patients with cancer than among those without cancer (**Supplementary Table S2**). These problems highlight the fact that cardiovascular diseases become more important during the long-term survival of patients with cancer. Advances in screening, big data, targeted and immune therapies, and significant new knowledge of cancer biology are changing the prevention, detection, diagnosis, treatment and survival of cancer. However, the current treatments are still mostly based on extrapolation from non-cancer patient data, and there remain some gaps in achieving the goal of personalized treatment for AMI patients with cancer.

### **Patients With a Historical Cancer Diagnosis Within 5 Years Had a Higher Risk of Adverse Cardiovascular Outcomes Among All Subgroups**

Furthermore, subgroup analysis was performed according to the time between the diagnosis of cancer and the occurrence of AMI. The results showed that the incidences of all-cause death, cardiovascular death and MACCE in the group with a historical cancer diagnosis within 5 years were significantly higher than in those without cancer, and the risks in that subgroup were the highest among all subgroups. This connection is not accidental, and a large-scale study from Sweden also found that patients with cancer had the highest risk of CHD in the first 6 months after diagnosis (23). Another previous study reported similar results: the risks of in-hospital mortality and MACCEs were higher by at least 50% among AMI patients with a current cancer diagnosis than among those without cancer, whereas they were not higher among patients with a historical cancer diagnosis (21). Our findings also underscore the importance of vigilance in cardiovascular risk monitoring after cancer treatment. It is critical to continue assessing the risk of potential cardiovascular events among patients with cancer, and future randomized trials are needed to evaluate the effectiveness of such surveillance.

### **Limitations**

(a) We acknowledge all limitations inherent to a retrospective, single-center study, which restrict the generalization of our

findings and the inference of causality. (b) The overall cancer population was relatively small, and the subgroups related to cardiovascular safety concerns were potentially underpowered. In addition, the patients with cancer were a heterogeneous population with different cancer types and stages, and the sample size was too small to evaluate each cancer type separately. (c) Although the data for AMI patients were abundant, the lack of complete cancer history and cancer types may be considered a limitation of this study. The missing data on cancer metastasis, stages, and cancer treatment limits the further understanding of the differences in outcomes between AMI patients with cancer and those without cancer.

## **CONCLUSIONS**

AMI patients with cancer tended to have a significantly higher risk of cardiovascular adverse outcomes than those without cancer. Given the limited evidence-based guidance, clinicians are more likely to empirically initiate conservative treatment when faced with the dilemma of ischemia and the risk of major bleeding. Thus, it is vital to raise awareness of cardiovascular risk management and continuously optimize cardiovascular treatment among patients with cancer.

Advances in tumor diagnosis and treatment, especially the use of targeted therapies, have remarkably improved the survival rate of patients with renal cell carcinoma (RCC), accompanied by higher hypertension (HTN) incidence among patients with RCC, reflecting the coming of a cardio-oncologic era. Therefore, for patients with RCC and HTN simultaneously, finding risk factors for the comorbidity and giving better clinical treatment have been urgent problems. In this review, we thoroughly investigated risk factors for the comorbidity of HTN and RCC based on preclinical and clinical studies. Firstly, RCC and HTN may have common risk factors, such as obesity, smoking, and other modifiable lifestyles. Secondly, RCC and HTN may lead to each other directly or indirectly by their therapies. We then discussed measures of reducing the comorbidity and treatment of HTN in patients with RCC. We also discussed the deficiency of current studies and pointed out future directions. In conclusion, this review aims to deepen the understanding of cardio-oncology and bring benefit to the population who are at high risk of getting or have already got RCC and HTN simultaneously.

**Keywords:** hypertension, kidney cancer, comorbidity, targeted therapy, antihypertensive drug, cardio-oncology

## INTRODUCTION

The prevalence of hypertension (HTN) and renal cell carcinoma (RCC) keeps increasing. In 2019, one-third of people between 30 and 70 years old were estimated to have HTN globally and the number has doubled from 648 to 1.2 billion in the past 3 decades (1). HTN was the most frequent comorbidity with malignant tumors, seen in 38% of patients with cancer (2). RCC accounted for about 90% of renal malignancies (3). According to GLOBOCAN in 2020, the patients with kidney cancer were more than 1.2 million and new cases were estimated to be 431,288 globally (4). RCC prevalence in the United States was increasing owing to a higher incidence which had doubled compared with the incidence in 1975 (15.6 vs. 7.1 per 100,000 persons) and longer 5-year relative survival (75.6 vs. 52.3%), reported by the SEER program (5).

Since the prevalence of HTN and RCC is increasing, patients with RCC and HTN simultaneously are estimated to increase for the following reasons: HTN is a potential risk factor for RCC (6) and RCC can cause HTN due to paraneoplastic syndrome (7), nephrectomy (8), and targeted therapies (9). Besides, prolonged survival rates and modern lifestyles may increase the comorbidity of HTN and RCC (10). The above-mentioned situation raised our questions: (1) What are the risk factors for the comorbidity of HTN and RCC in cardio-oncologic era? (2) How to decrease the comorbidity of HTN and RCC? (3) How to give better antihypertensive treatment for the patients with RCC with HTN? To answer these questions, we did a thorough search and reviewed the relationship between HTN and RCC based on clinical evidence and basic researches (**Figure 1**).

## METHODS

A literature review of publications about RCC and HTN has been performed. A manuscript outline was formed before searching for relevant publications. PubMed (1946–2021) and Cochrane Library (1996–2021) were employed as the source of initial searches. Hand searching was also used to find relevant studies in PubMed and other websites (e.g., FDA and SEER). Besides, valuable publications recommended by experts were included as well. Key search words include HTN, antihypertensive agents, and kidney neoplasms. Detailed search queries and search results are available (**Supplementary Material**). In total, 7,279 studies were found. These studies were screened for eligibility using title and abstract. The remaining studies were then retrieved as full texts and checked with inclusion and exclusion criteria. We considered studies that were related to: (1) epidemiology about RCC or HTN; (2) risk factors causing RCC or HTN; (3) mechanisms for the formation of RCC or HTN; (4) treatment of HTN in patients with RCC. We excluded studies that were: (1) not in English; (2) duplicate; (3) clinical studies with similar results but lower evidence level or out of date; and (4) could not find full text. The review process is conducted independently by 3 authors. Discrepancies were solved by consensus.

## COMMON MODIFIABLE RISK FACTORS

Obesity, inadequate physical activity and alcohol are well-known dose-dependent risk factors for HTN (11). The relationship between smoking and HTN is complex, but it is certain that cessation of smoking can dramatically reduce the cardiovascular disease burden (12). It is noteworthy that obesity, smoking, and inadequate physical activity are also risk factors for RCC (13)

**Abbreviations:** ACEI, angiotensin-converting enzyme inhibitor; a-MSH, a-melanocyte-stimulating hormone; ARB, angiotensin receptor blockade; BMI, body mass index; BP, blood pressure; CCB, calcium channel blocker; DBP, diastolic blood pressure; HR, hazard ratio; HTN, hypertension; IGF-1, insulin-like growth factor-1; mRCC, metastatic RCC; mTOR, mammalian target of rapamycin; OR, odds ratio; OS, overall survival; PFS, progression-free survival; PN, partial nephrectomy; RCC, renal cell carcinoma; RR, relative risk; RN, radical nephrectomy; SBP, systolic blood pressure; tHTN, targeted therapy-related HTN; TKI, tyrosine kinase inhibitor; VEGF, vascular endothelial growth factor; VSP, vascular endothelial growth factor signaling pathway.

while alcohol exerts a protective effect on RCC development (14). Besides, diets play important roles in HTN and RCC. For example, excess salt intake increases blood pressure (BP) (11), whereas heavy meat and fatty food are risk factors for RCC, and lack of vegetables or fruits may also increase RCC incidence (15), but the common unhealthy diets for both RCC and HTN still need further study. In summary, obesity, smoking, and inadequate physical activity are common modifiable risk factors for RCC and HTN, we will discuss the clinical evidence and potential mechanisms below.

## Obesity as a Risk Factor for RCC

A meta-analysis of 24 cohort studies showed that the relative risk (RR) of kidney cancer was 35% higher ( $RR = 1.35$ , 95%  $CI = 1.27-1.43$ ) in overweight [body mass index (BMI): 25–30] and 76% higher (1.76, 1.61–1.91) in patients of obesity (BMI > 30) compared with the normal weight population (16). Several indicators of obesity were used in clinical studies, such as BMI, waist and hip circumference, and body fat percentage, but the results were consistent (15). A large cohort study demonstrated that per unit increase in BMI will increase 5% risk of RCC (17). Both pre-existing obesity in adulthood and obesity near diagnosis of RCC could increase the risk of renal cancer [odds ratio (OR) = 1.6, same] (18). Of note, a cohort study in Japan demonstrated that low BMI (<21) may also increase the risk of kidney cancer [hazard ratio (HR) = 1.86; 95%  $CI$ : 1.01–3.45] compared with BMI of 23.0–24.9 (19). Interestingly, obesity was found to increase the risk of clear-cell RCC while decreasing the risk of papillary RCC (14). Such heterogeneity may be associated with demographic difference considering the fact that papillary RCC is more common in women, the older and the black (20).

Obesity-induced chronic renal hypoxia may play an oncogenic role mainly through upregulating the vascular endothelial growth factor (VEGF) pathway (21). Obesity could cause lipid peroxidation and then facilitate the formation of RCC (22). Obesity-induced renal hyperfiltration may increase the exposure to oncogenic nephrotoxins (23). Increased estrogen in adiposity patients also facilitates RCC by upregulating the insulin-like growth factor-1 (IGF-1) receptor, enhancing the oncogenic influence of IGF-1 (24). Metabolism disorders caused by obesity are also oncogenic. Overexpressed insulin and IGF-1 could promote the formation of RCC. Adiponectin, secreted by fatty tissue, is an anti-angiogenic factor by suppressing the VEGF pathway. However, the serum adiponectin is expressed lower in obesity (15). Besides, increased leptin in obesity, which is a kind of adipokine, promotes RCC by regulating VEGF, the Janus kinase/signal transducer and activator of transcription 3 and extracellular signal-regulated kinase 1/2 pathways (25). Obesity-induced inflammatory response increases levels of interleukin-6, which is also an oncogenic adipokine because it can protect RCC cells from immune attacks (26).

Insulin resistance and increased circulating insulin observed in obesity could induce HTN by increasing renal sodium reabsorption and activating the sympathetic nervous system (27). Elevated leptin can also promote HTN mediated by increasing

sympathetic nervous system activity (28). Furthermore,  $\alpha$ -melanocyte-stimulating hormone ( $\alpha$ -MSH) that is a hormone secreted by melanocytes could regulate BP by suppressing adrenocorticotrophic hormone. Interestingly,  $\alpha$ -MSH could also inhibit obesity progress by targeting melanocortin 4 receptor. Therefore, it is hypothesized that sunshine may increase levels of  $\alpha$ -MSH and then protect obese patients from inflammation-induced HTN (29).

### Smoking as a Risk Factor for RCC

A meta-analysis of 24 studies reported that smokers have a higher risk for RCC ( $RR = 1.38$ , 95%  $CI: 1.27-1.50$ ) and a dose-dependent relationship was seen both in men and women (30). Remarkably, passive smoking increases the risk of RCC either (31). Cessation of smoking for more than 30 years reduced 50% risk of RCC ( $CI: 0.3-0.8$ ), while quitting smoking shorter than 30 years showed no significant difference in RCC incidence (32). A retrospective study revealed that smoking is positively related

to increased risk of clear-cell RCC rather than papillary RCC. However, this heterogeneity may be attributable to the skewed distribution of smoking patterns (14).

Some ingredients contained in cigarettes are carcinogenic. Nicotine could induce angiogenesis of RCC, while N-nitrosamines and Benzo[ $\alpha$ ]pyrene diol epoxide correlate with renal oxidative stress which could lead to DNA damage or gene aberration, thus facilitating the formation of RCC (15). Smoking-related chronic respiratory diseases and carbon monoxide could cause hypoxia of renal tissue (10) and lipid peroxidation is another possible mechanism (22).

Grassi et al. (33) found that smoking-induced acute increase of BP attributes to higher dose of catecholamines at the neuroeffector junctions. In addition, smoking was demonstrated to cause increased arterial wave reflection and stiffness of large arteries, thus enhancing BP (34). Smokers with atherosclerotic renal artery stenosis were more common than non-smokers, and renal vascular stenosis could cause refractory HTN (35).

## Low Physical Activity as a Risk Factor for RCC

Low physical activity is regarded as a risk factor for RCC (36–38). An American cohort study of 482,386 participants with a median follow-up of 8.2 years showed that the multivariate RR for those with current exercise more than 4 times per week was 0.77 (95% CI: 0.64–0.92) compared with the never exercise population. Besides, regular exercise and activity in youth is also protective (36). Similarly, a meta-analysis including 19 studies, which was conducted in 2013, showed that adequate physical activity was a protective factor for RCC (RR = 0.88, 95% CI: 0.79–0.97) (37). Physical activity like running or walking had a dose–response relationship with a decreased risk (1.9% risk decline per metabolic equivalents hour/week) of kidney cancer after adjustment for age and sex (38).

Physical activity may decrease the risk of RCC in a directly or indirectly manner. Physical activity could directly inhibit RCC formation by decreasing insulin resistance, circulating IGF-1, and lipid peroxidation (37). Some researchers thought the lack of exercise was an indirect risk factor because a low level of energy consumption could cause obesity and subsequently promotes RCC formation (13). Furthermore, more activity could prevent HTN and diabetes, which are also confounding factors (38).

The mechanisms for inactivity-induced HTN have not been clearly demonstrated. Murine studies showed that insulin resistance and imbalance of sympathetic and vagus nerves are potential reasons (39). Another animal study demonstrated that resistance training could contribute to the regulation of vessel constriction and keep luminal diameter (40). Other factors that explain inactivity-induced HTN include vascular resistance, arterial stiffness, oxidative stress, inflammation, BMI, and endothelial function (41).

## HTN AS A DIRECT RISK FACTOR FOR RCC

A meta-analysis of 18 prospective studies and 14 case–control studies showed that each 10 mmHg increase of systolic BP (SBP) led to 5% higher risk (95% CI: 1.03–1.06) of RCC and 10 mmHg increase of diastolic BP (DBP) with 7% higher risk (95% CI: 1.04–1.10) (42). However, extremely high pressure (SBP > 150 mmHg or DBP > 100 mmHg) will cause a rapid increase of RCC incidence rather than linear growth (6, 43). It is noteworthy that even high-normal BP (SBP: 130–140 mmHg, DBP: 80–90 mmHg) could increase the risk of RCC (44).

Women with HTN may be more susceptible to RCC. A recent meta-analysis showed that women with HTN have a 54% higher risk than men (RR = 63 vs. 29%), but the difference was substantially reduced (1.40, 1.12–1.74 for men and 1.54, 1.17–2.04 for women) after adjustment for age, cigarette, family history of RCC, obesity, alcohol, and physical activity (42).

Age may influence the incidence of RCC in the patients of HTN while this hypothesis is still controversial. A study suggested that HTN was not an independent risk factor for RCC in adolescence (45), while another study got the opposite conclusion that younger patients with HTN were more likely to develop RCC (44).

It is worth mentioning that HTN may have a synergistic effect with obesity on RCC formation. A prospective study showed that the risk of obesity-caused RCC will increase significantly when BP was very high (SBP > 160 mmHg or DBP > 100 mmHg) (6).

A cohort study conducted in Sweden with a mean follow-up of 16 years among 3,63,992 men using repeated measurements of BP showed that RCC incidence decreased with the reduction of BP and especially, in those with a reduction of more than 14 mmHg in DBP, the RR for RCC decreased 40% (46). Thus, HTN is a modifiable risk factor for RCC and effective control of BP is of great value.

However, some factors may influence the reliability of these researches. HTN shares several common risk factors with RCC (43), which highlights the necessity of sufficient adjustment for these confounding factors during the investigation of the causality between HTN and RCC. Besides, the way of defining and measuring HTN varies (47). Of note, if RCC were diagnosed in patients with HTN in the first several years after enrollment in a cohort, it is difficult to determine the occurrence sequence of RCC and HTN. But such bias could be avoided by excluding data of the first several years of follow-up (46). In conclusion, well-designed prospective studies are warranted to clarify their causality.

As to the mechanisms of HTN-induced RCC, HTN could result in chronic inflammation, making the kidney in a state of hypoxia and then upregulating the expression of hypoxia-inducible factors, causing overexpressed VEGF and platelet-derived growth factors which could facilitate the tumor genesis (2). Overexpressed angiotensin receptors and angiotensin-converting enzyme in the patients with HTN could upregulate the angiotensin II, and cause the overexpression of oncogenic VEGF (42, 48). In addition, HTN is related to dysfunction and remodeling of blood vessels, which could increase the number of reactive oxygen species and eventually promote the formation and progress of tumor (44). Similar to obesity, an increased level of lipid peroxidation in the patients of HTN is supposed to participate in RCC carcinogenesis (22).

## ANTIHYPERTENSIVE DRUGS AS A POTENTIAL RISK FACTOR FOR RCC

In general, antihypertensive drugs are not risk factors for cancers (49). However, a recent cohort study in Korea showed that the use of antihypertensive drugs in patients of HTN was related to increased risk of RCC (HR = 1.74, 95% CI: 1.64–1.84) and those with two or more classes of antihypertensive drugs have an even higher risk (HR = 1.80, 95% CI: 1.69–1.91) without adjusting for HTN (44). Another cohort study supported this result after adjusting for HTN, sex, age, BMI, and smoking (6). There seemed to be a linear relationship between the RCC incidence and the duration of antihypertensive drugs, and the risk will increase 2% per year (95% CI: 1.01–1.02) (50). However, different kinds of antihypertensive drugs play different roles in RCC development. Diuretics have been convincingly shown to be tumorigenic for kidney, while angiotensin-converting enzyme inhibitor/angiotensin receptor blockades (ACEI/ARBs)

are possible anti-cancer drugs. The role of calcium channel blockers (CCB) and  $\beta$ -blockers is still in dispute. The tumorigenic role of these antihypertensive drugs will be elaborated below.

## Diuretics

Many researchers argued that diuretics are risk factors for RCC (47, 48, 50–53). A systematic review of observational studies in 2020 found that diuretics could increase 34% RCC risk (95% CI: 1.19–1.51) (50). Another meta-analysis showed that the risk effect of diuretics was still significant after adjustment for smoking, obesity, and HTN (47). Several cohort studies and case-control studies drew similar conclusions (48, 51). Women with diuretics (OR = 1.92, 95% CI: 1.59–2.33) seemed to have a higher risk of RCC than men (OR = 1.18, 95% CI: 0.93–1.49) (47). The sexual difference may be explained by the hypothesis that estrogens could intensify the effect of thiazide in the distal tubule, and women consume more diuretics than men (52). Some possible underlying mechanisms may explain the carcinogenic role of diuretics. First, hydrochlorothiazide could be converted in the stomach to nitroso derivatives and cause genetic mutations (53). Second, diuretics may exert a little carcinogenic function on their target, the renal tubular cells (51). More detailed preclinical studies are necessary to clarify the possible tumorigenic mechanisms of diuretics.

## Calcium Channel Blockers

The role of CCB on RCC carcinogenesis has not been determined yet (54). In patients without HTN, the use of CCB increased the risk of papillary RCC rather than clear-cell RCC, demonstrated by a retrospective study (55). CCB may predispose the patients with HTN to RCC by impeding DNA fragmentation and cell apoptosis (44). However, other clinical studies showed insignificant results which denied its carcinogenic role (54).

## $\beta$ -Blockers

The role of  $\beta$ -blockers for RCC incidence is less well-studied. A recent cohort study showed that  $\beta$ -blockers have higher HR for RCC than other antihypertensive drugs (44). However, another large cohort study showed that  $\beta$ -blockers may not increase the risk of total cancer incidence (56). Thus, the exact role of  $\beta$ -blockers as a possible cancer-promotor is far from clear.

## Angiotensin-Converting Enzyme Inhibitors/Angiotensin Receptor Blockades

The role of ACEI/ARBs is still in dispute (57). A meta-analysis showed that ACEI increased the risk of RCC (RR = 1.50, 95% CI: 1.01–2.23) (58). ACEI may increase the amount of bradykinin which may facilitate RCC formation (57). Interestingly, ACEI/ARBs are also considered as possible anti-cancer drugs since overexpressed angiotensin receptors and angiotensin II is associated with upregulated VEGF (59).

Even though many clinical studies have managed to clarify the causality between antihypertensive drugs and RCC, there are still no conclusive results because of some limitations. Firstly, it is quite difficult to exclude the effect of HTN *per se* (10). For example, a large prospective study in 2008 showed that in those with SBP < 160 mmHg or DBP < 100 mmHg, the use

of antihypertensive drugs did not show a significant difference compared with non-users while in those with poorly controlled BP, antihypertensive medication increased the risk of RCC, which highlighted the confounding role of HTN (6). Secondly, other confounding factors like age, sex, obesity, smoking, and physical activity are sometimes not adjusted because of the small sample size or poor statistical design. Thus, a well-designed large prospective clinical study is needed to clarify the relationship between antihypertensive drugs and RCC.

## RCC DIRECTLY CAUSE HTN

The HTN directly caused by RCC is considered as a manifestation of paraneoplastic syndrome and in the population with malignant HTN, the prevalence of RCC was 1.2%, much higher than those without malignant HTN (0.01%) (7), indicating malignant HTN could be a clue for the diagnosis of RCC. The severity of paraneoplastic HTN varies and can sometimes cause refractory HTN. Most of the paraneoplastic HTN will recover after nephrectomy (60–62).

Tumor compression, renal arteriovenous fistula, and ureteral obstruction could cause renal ischemia, thus activating the ren-angiotensin-aldosterone system, leading to HTN (63, 64). Besides, ectopic hormones secretion, such as catecholamines, erythropoietin correlated with paraneoplastic HTN (7, 60). Hypercalcemia, which increased vascular resistance or indirectly increased catecholamines, could also cause HTN (61, 62). In addition, paraneoplastic nodular polyarteritis correlated with renal vascular HTN (59). It is rarely reported that brain metastasis from RCC could cause intracranial HTN by compressing dural venous sinuses (65).

## TREATMENT OF RCC CAUSE HTN

The treatment of RCC mainly includes surgery for localized RCC, targeted therapy, and immunotherapy for metastatic RCC (mRCC) (3). The excision of kidney jeopardizes kidney function and then increases the risk of cardiovascular disorders, such as coronary heart disease, HTN, cardiomyopathy, heart failure (HF), and dysrhythmias (66). Considering that partial nephrectomy (PN) can better preserve kidney function than radical nephrectomy (RN), PN is recommended to treat patients with early stage tumors (3). Nephrectomy-related HTN (NR-HT) has been reported by several studies, but robust high-level evidence is still needed (8, 67–69). The use of targeted therapies, especially vascular endothelial growth factor signaling pathway (VSP) inhibitors, has remarkably increase the life expectancy of patients with mRCC while the increased risk of cardiovascular events turns out to be its obvious side effect (5, 70). Apart from HTN, VSP inhibitors could also cause venous thromboembolism (VTE), HF, arterial thromboembolism (ATE), myocardial infarction (MI), long Q-T syndrome (LQTS) and Torsade de Pointes (TdP). Detailed information is listed in **Table 1**. Immunotherapy is also a first-line therapy for mRCC but significant cardiovascular side effects have not been found yet (3, 70).

**TABLE 1** | Incidence of targeted therapy associated hypertension (HTN) in patients with metastatic renal cell carcinoma (mRCC).

Drugs	FDA approved year	Any grade HTN (%)	Grade 3/4 HTN (%)	Other associated cardiovascular complications
Temsirolimus	2007	7	-	VTE, thrombophlebitis
Everolimus	2009	1–10	3	Non-infectious pneumonitis with pulmonary HTN, VTE, tachycardia, HF
Bevacizumab	2004	4–34	1–11	ATE, VTE, HF
Sorafenib	2005	12–34	4–11	MI, LQTS
Sunitinib	2006	24–41	8–15	MI, HF, cardiomyopathy, LQTS, TdP
Pazopanib	2009	13–57	4	LQTS, TdP, HF, ATE, VTE, thrombotic microangiopathy
Axitinib	2012	40–42	8–16	ATE, VTE, HF, MI
Lenvatinib	2015	42	13	cardiomyopathy, HF, ATE, LQTS
Cabozantinib	2016	37–81	15–28	MI, ATE, VTE
Tivozanib	2021	44–45	12–22	HF, MI, ATE, VTE

This table shows data about incidence of tHTN collected from FDA, Phase III clinical trials and meta-analysis or other high-grade evidences. The Grade 3/4 HTN data about Temsirolimus has not been found. HTN, hypertension; VTE, venous thromboembolism; HF, heart failure; ATE, arterial thromboembolism; MI, myocardial infarction; LQTS, long Q-T syndrome; TdP, Torsade de Pointes.

## Nephrectomy-Related HTN

As for PN, a cross-sectional survey showed that PN was independently associated with NR-HT ( $OR = 2.93$ ,  $p = 0.022$ ) (8). There are several hypotheses for NR-HT after PN. The compressed renal parenchyma due to renal hematoma, bolsters, or sclerotic tissue could cause insufficient renal perfusion and renin-angiotensin system activation, which refers to the “page kidney” hypothesis (71). In addition, vascular clamping in PN process could cause vasculitis and intimal hyperplasia, which would aggravate renal artery stenosis, resulting in the decline of glomerular capillary pressure and activated rennin-angiotensin system, leading to NR-HT (72). However, some studies drew opposite conclusions (67, 73). A retrospective study involving 264 patients with PN showed that BP had no significant change after surgery (67). A plausible explanation is that PN may treat paraneoplastic HTN, which can mask NR-HT, thus resulting in a statistically insignificant difference. Another study showed the BP decreased 1.9 mmHg ( $p = 0.01$ ) in 5 years after PN and the decrease of BP is thought to be associated with more BP measurements during follow-up and increased antihypertensive medications (73). Considering the conflicting results, well-designed prospective researches are warranted for NR-HT.

As for RN, it is still uncertain for its facilitating HTN role owing to insufficient evidence. After more than 10 years of follow-up, a small cohort study showed that 40% of patients with RN developed NR-HT and the mechanisms of RN leading to NR-HT are most likely due to functional renal parenchyma deficits and secondary end-stage renal disease (68). However, another cross-sectional cohort study showed that there was no significant difference in BP among RCC patients who underwent RN (69). Besides, the circadian rhythm of BP may also be affected after bilateral RN (74).

## Targeted Treatment-Related HTN

Targeted therapies for mRCC have prolonged the overall survival (OS) and progression-free survival (PFS) significantly and now have been listed as the standard treatment for mRCC (3). However, the number of patients with mRCC complicated with

targeted therapy-related HTN (tHTN) as the on-target effect has dramatically increased (75).

These targeted drugs for mRCC mainly include VSP inhibitors and phosphatidylinositol-3-kinase–protein kinase B/mammalian target of rapamycin (mTOR) inhibitors. Bevacizumab is a monoclonal antibody to VEGF, often accompanied by the use of IFN- $\alpha$  (3). Multitargeted tyrosine kinase inhibitors (TKIs), which can bind to VEGF receptors and suppress the VEGF pathway, include sunitinib, sorafenib, pazopanib, axitinib, tivozanib, and cabozantinib (76). The mTOR inhibitor includes everolimus and temsirolimus (3). According to a report of real-world treatment patterns, the most common first-line used of targeted drugs in 2015 in the United States are sunitinib and pazopanib accounting for about 70% (77).

Strong evidence showed that targeted therapy, especially VSP inhibitors, could induce HTN. We collect data about tHTN from FDA (70), Phase III clinical trials, meta-analysis, or other high-grade evidence RCC (78–84) (Table 1). The Common Terminology Criteria for Adverse Events classified the tHTN into 5 grades. A meta-analysis of randomized controlled trials in 2015 showed that patients with TKIs have a significantly higher grade 3 or 4 HTN incidence compared with IFN- $\alpha$  or placebo ( $RR = 6.00$ , 95%  $CI$ : 3.36–10.69) (9). A large retrospective real-world study from 2006 to 2015 showed the total tHTN incidence rate was 69.1 per 100 patient-years and VSP inhibitors were higher than mTOR inhibitors (71.7 vs. 47.8 per patient-years) (77). The newer generation of VSP inhibitors which are more powerful to inhibit the VEGF pathway, tended to have higher HTN incidence (85). In addition, higher doses and longer duration of VSP inhibitors will increase the incidence and degree of HTN, which showed a dose-dependent relationship (2, 85, 86). Germline polymorphisms (86), high SBP at baseline (87), aging and other cardiovascular risk factors (88) may also affect the onset of tHTN. The tHTN could occur within hours or days after receiving VSP inhibitors (9) and drop quickly after drug withdrawal (89). The average onset time of tHTN was 131 days for bevacizumab (78), 116.5 days for mTOR inhibitors, and 70.0 days for VSP inhibitors (77). The newly proved lenvatinib has a median onset time of 35 days, reported by the FDA (70).

The use of antihypertensive drugs may affect the onset time of severe HTN (9).

The mechanisms for tHTN are still elusive. VSP inhibitors could cause depletion of nitric oxide and prostacyclin which are vasodilators as well as increased vasoconstrictive endothelin-1 (89). In addition, increased reactive oxygen species, functional decreased microvascular density, increased vascular stiffness, and salt sensitivity are other possible reasons (90).

The tHTN could be seen as a biomarker for the on-target effect of VSP inhibitors and indicated a better prognosis (75). A multicenter retrospective study in 2020 demonstrated that patients with tHTN had higher PFS (12 months, 95% CI = 9–21 months) than those without tHTN (9 months, 95% CI: 7–12 months) (86). Similar results were shown among other TKIs and Bevacizumab (2, 75).

However, HTN that is not induced by targeted therapy could increase the risk of RCC mortality (OR = 1.75, 95% CI: 1.61–1.90) demonstrated by a review such as 6,964 patients of RCC in 2002 (91). Severe HTN in patients of RCC could cause HF, leukoencephalopathy, suspend, or cessation of targeted drugs (75, 90), which will do harm to the prognosis and well-control of BP during targeted therapy could improve prognosis (92).

## Selection of Antihypertensive Drugs for tHTN

There is no conclusion about the best antihypertensive drugs for tHTN (81). The current opinion is the selection of antihypertensive drugs should be individualized, but there are indeed some preferences (93).

Angiotensin-converting enzyme inhibitors/ angiotensin receptor blockades are potential better antihypertensive drugs for VSP inhibitors users. Several retrospective studies showed that patients of mRCC treated with sunitinib or other VSP inhibitors had better OS and PFS if received ACEI/ARBs (92, 94). ACEI/ARBs may be more recommended in patients with mRCC undergoing nephrectomy, considering its renal protective function (95). ACEI/ARBs could also treat proteinuria and left ventricular systolic dysfunction induced by targeted treatment (81, 90). ACEI/ARBs may prevent sarcopenia in patients with RCC and then reduce overexposure and toxicity of TKIs which could decrease the treatment interruption rate (95). However, a case report claimed that ACEI may decrease the effect of bevacizumab in ovarian cancer (96) and another case reported that combinatorial therapy of ACEI and everolimus may increase the risk of angioedema (97). A pooled-analysis reported that baseline use of ACEI/ARB is not significantly associated with OS or PFS (81). Thus, even with much supporting evidence, the priority of ACEI/ARB in mRCC needs further studies.

Dihydropyridine CCB can control tHTN as well as other antihypertensive drugs, considering the function of inhibiting arterial wall contractility (98). In addition, CCB was thought to inhibit chemoresistance of RCC and thus enhance drug efficacy (88). Besides, animal studies showed that CCB could increase the density of micro-vessels (89). But non-dihydropyridine CCB should not be used in patients receiving VSP inhibitors because

they would competitively inhibit the activity of P450 3A4, thus increasing the circulating VSP inhibitors concentrations (2).

A retrospective study showed that the patients with mRCC treated with sunitinib or pazopanib with  $\beta$ -blockers have better PFS and OS than other antihypertensive drugs (99). Animal studies have shown that  $\beta$ -blockers could inhibit the proliferation of cancer, but the anti-cancer role of  $\beta$ -blockers in human is still in controversy (100).

The use of diuretics should consider the probability of dehydration and electrolyte disorders, since patients treated with VSP inhibitors like sunitinib have the higher risk of diarrhea and electrolyte imbalances (95). Fluid retention due to sodium excretion depletion may explain tHTN occurred weeks later and diuretics are a potential preference in this condition (101).

## DISCUSSION

### What Are the Risk Factors for Comorbidity of HTN and RCC?

The relationship between HTN and RCC is complex (**Figure 1**). HTN and RCC share several common modifiable risk factors, such as obesity, smoking, and low physical activity. These risk factors may induce RCC and HTN through several common mechanisms, for example, chronic inflammation, oxidative stress like lipid peroxidation, interleukin-6, insulin, IGF-1, leptin, and VEGF pathway (48). There are also some potential common risk factors, like unhealthy diet, alcohol, but need further study to confirm their roles.

Hypertension is a direct risk factor for RCC with a dose-dependent relationship. HTN may also play a synergistic role with other risk factors like obesity to facilitate RCC. Meanwhile, the risk of RCC caused by antihypertensive drugs has not been excluded and diuretics are with great suspicion to cause RCC. Notably, ACEI/ARBs are potential anti-cancer drugs considering their mechanisms of function.

Renal cell carcinoma can directly cause HTN by the formation of arteriovenous fistula, tumor compression-induced renin secretion, ectopic hormone syndromes, paraneoplastic vasculitis, and brain metastasis. Treatment of RCC can also induce HTN. Nephrectomy may affect BP. The use of targeted therapy is strongly associated with HTN. This kind of increased BP is short-term, reversible, and dose-dependent and indicates the effect of targeted therapy. As to medicine for tHTN, there is no strong evidence proving a preference for a certain kind of antihypertensive drugs.

There are some guiltless factors responsible for the increasing comorbidity. For example, population growth and aging, advances in cancer treatment and prolonged survival, widespread use of advanced imaging techniques, improved public awareness for annual medical examination (44, 48, 102).

### How to Decrease the Comorbidity of HTN and RCC?

There are some factors that we can handle to decrease the comorbidity and the suggestions are discussed below (**Figure 2**).

Obesity, smoking, and lack of physical activity all show a dose-dependent relationship with RCC and HTN. Obesity was supposed to be associated with 78% patients of HTN, and increased 60% risk of RCC (90). The risk of RCC doubled in people smoking more than 20 cigarettes a day while cessation of smoking more than 30 years reduced the 50% risk of RCC (32). Adequate physical activity can reduce 12% risk of RCC (37). It is known that prevention is more favorable than treatment, both for patients and for society. Thus, public awareness of developing a healthy lifestyle should be raised and effective public health policies should be implemented to reduce the modifiable risk factors.

Poor control of essential HTN facilitates the rising prevalence of RCC. Globally, it is estimated that only half patients of HTN are diagnosed and one-fifth patients of HTN have well-controlled BP (1). Thus, improvement of the awareness and treatment rate of HTN is quite urgent.

Diuretics exert a potential carcinogenic effect, thus it should be prescribed after comprehensive thought of the risk/benefit ratio (103). For those with severe HF, refractory HTN, or edema, the benefit is higher than the risk. Considering the carcinogenic risk of diuretics is low and needs long-term accumulation to be significant, younger women who

need decades of use of diuretics are at high risk than the elderly and if not necessary, better change to other antihypertensive drugs.

For those with obesity, smoking exposure, low activity, and unhealthy diets, the risk of RCC or HTN is high. For those with long-term HTN and diuretics history, RCC will occur in higher possibility. People with malignant HTN also have a higher incidence of RCC (7). These groups with a high risk of RCC are recommended for regular renal imaging examination. And for those already diagnosed with RCC and HTN, cardio-oncologic teams are needed to give better clinical care.

## How to Give Better Antihypertensive Treatment for the Patients With RCC With HTN?

Regular and accurate BP measurement is fundamental. If the patients with RCC are treated with nephrectomy and targeted therapy, clinicians need to predict the possible changes of blood pressure and monitor BP regularly. As to tHTN, guideline recommend well-controlled BP before targeted treatment and weekly monitor during the first treatment cycle and monitor every 2–3 weeks in the remaining treatment cycle (76). For

those with a history of HTN or coronary heart disease, the risk of cardiovascular event is significantly higher when receiving VSP inhibitors and should be monitored with caution (104). Hypotension may also occur as a manifestation of hypersensitivity/infusion reactions when receiving targeted therapy (70). Thus, BP should be monitored throughout the infusion process and necessary supportive care should be prepared. Notably, white-coat HTN, masked HTN may conceal the exact BP, so out-of-office measurements are also necessary (105).

Well-control of BP can improve the prognosis of RCC by preventing severe cardiovascular diseases or discontinuation of targeted drugs (104). The HTN caused by VSP inhibitors is usually mild and reversible (106). According to ACC/AHA guidelines, for people taking VSP inhibitors, the recommended BP is below 140/90 and below 130/80 if with cardiovascular risk factors (105). However, there is limited evidence to support this antihypertensive target. The patients with RCC with VSP inhibitors developed stage I HTN or DBP increased >20 mmHg should use antihypertensive drugs (107). The pros and cons of each kind of antihypertensive drugs have been discussed above. If the HTN could not be controlled well with a single agent, consider combined therapy methods. If the HTN is uncontrolled with end organ damage, the cessation of VSP inhibitors is recommended (108). Paraneoplastic HTN is usually reversible after renal tumor removal and there is a lack of evidence for antihypertensive therapies for NR-HT. Besides, better pain control and psychotherapy are necessary in the control of BP in the patients with RCC (2).

However, in view of the lack of high-level evidence for the management of HTN in the patients with RCC and different comorbidity conditions of patients, the strategy of blood pressure control is often best guided by a team of oncologist, cardiologist, and clinical pharmacist (108). It is necessary to improve the understanding of “cardio-oncology” among health professionals. The term “cardio-oncology” highlights the complex relationship between cardiovascular diseases and cancer, and encourages the corporation of cardiovascular specialists and oncologists to give better clinical care for cancer survivors.

## CONCLUSIONS

In modern society, owing to the change of lifestyle and use of VSPs, the number of patients with HTN and RCC simultaneously is increasing, which turns out to be a heavy disease burden. This review thoroughly investigated the relationship between RCC and HTN from basic, epidemiological, and clinical aspects, aiming to deepen the understanding of the comorbidity and benefit of these patients. However, many problems remain to be resolved. Apart from obesity, smoking, and low physical activity, there are still other possible common modifiable risk factors without robust evidence. Besides, the exact roles of antihypertensive drugs on tumor formation are uncertain and high quality evidence regarding the management of HTN secondary to RCC is far from enough to generate guidance for clinicians. Thus, we appealed to the corporation of basic scientists, public health officers, oncologists, cardiologists, and other health experts to solve these cardio-oncologic problems.

Left ventricular (LV) mass loss is prevalent in doxorubicin (DOX)-induced cardiotoxicity and is responsible for the progressive decline of cardiac function. Comparing with the well-studied role of cell death, the part of cardiomyocyte atrophy (CMA) playing in the LV mass loss is underestimated and the knowledge of the underlying mechanism is still limited. In this review, we summarized the recent advances in the DOX-induced CMA. We found that the CMA caused by DOX is associated with the upregulation of FOXOs and “atrogenes,” the activation of transient receptor potential canonical 3-NADPH oxidase 2 (TRPC3-Nox2) axis, and the suppression of IGF-1-PI3K signaling pathway. The imbalance of anabolic and catabolic process may be the common final pathway of these mechanisms. At last, we provided some strategies that have been demonstrated to alleviate the DOX-induced CMA in animal models.

**Keywords:** doxorubicin, cardiotoxicity, cardiomyocyte atrophy, left ventricular mass loss, cell death

## INTRODUCTION

Doxorubicin (DOX), the most prescribed anthracycline chemotherapy agent, remains one of the most commonly used anti-cancer drugs among the world while its clinical application is limited by its cumulative dose-dependent cardiotoxicity (1, 2). The congestive heart failure (CHF) is the end stage of DOX-induced cardiotoxicity (DIC) and predicts poor prognosis. The incidence of DOX-related CHF reaches to 26% in patients received DOX at a cumulative dose of 550 mg/m<sup>2</sup> (3). The health of patients with cancer and cancer survivors is threatened by the DIC, unfortunately, the number of both is large. For cancer survivors only, it was reported that there are more than 16.9 million cancer survivors until January 1, 2019 in the United States; this number is estimated to reach more than 22.1 million in the next decade based on the growth and aging of the population alone (4). Nowadays, several strategies are recommended for patients planning to receive high-dose anthracyclines to prevent DIC, such as the use of dexrazoxane or liposomal formulation of doxorubicin, continuous doxorubicin infusion (evidence based; strength of recommendation: moderate) (5). However, there is still lack of evidence to confirm whether these strategies are safe and effective for all patients with cancer receiving chemotherapy (5–7). Although small clinical

trials have revealed that conventional drug of heart failure therapy may be beneficial against DIC (8, 9). Cardinale et al. reported that with conventional heart failure therapy, only 11% patients showed complete recovery from DIC in a heterogeneous cohort study of 2,625 patients (10). Therefore, it is vital to uncover the key mechanism of DIC and find a new approach to prevent it.

Several studies have revealed that anthracycline-based chemotherapy (ANbC) accounts for the left ventricular (LV) mass loss in patients with cancer and cancer survivors. In patients receiving ANbC, the LV mass decrease was detected as early as 1 month after the initiation of the therapy (11) and a 5% reduction in LV mass in 6 month was found based on the cardiovascular magnetic resonance detection (12). In the studies focusing on the pediatric and adult cancer survivors, the LV mass reduction still exists more than 20 years after the ANbC therapy (13–17). The severity of LV mass loss is correlative with the cumulative dose of DOX (14, 18). Further, there may not be a safe dose of DOX to avoid cardiotoxicity for that the cardiac abnormalities, such as significantly reduced LV mass and dimension was found in patients who received as low as 45 mg/m<sup>2</sup> cumulative dose (18).

Although there are multi-factors that can be resulted into the LV mass loss, for example, cancer-associated cachexia like food intake reduction and excess catabolism (19), heart load alteration (20), denervation (21), and bed rest (22). Jordan et al. found that the reduction of LV mass is not necessarily accompanied with the decline of body weight and the heart failure (HF) symptom is not associated with the body weight decrease in patients who received ANbC, indicating a process other than cancer-associated cachexia leads to LV mass loss (12). Consistent finding was reported in animal models, DOX itself caused the heart weight loss in healthy mice and the heart weight (HW)/body weight (BW) index decreases in a dose-dependent fashion of DOX treatment, implicating the possibility that the HW loss is out of portion of BW loss and is caused by the chemotherapy (11). Intriguingly, Pietzsch et al. reported that the cardiac dysfunction induced by cancer alone would nearly recover to the base line, while tumor-bearing mice with DOX treatment showed lower survival rate in the acute phase and long-lasting damage in the gene expression system (23).

The LV mass loss is correlative to the decline of life quality (12) and the increase of major adverse cardiovascular events, such as cardiovascular death, implantable cardioverter-defibrillator therapy, and decompensated heart failure (14). Generally, the LV afterload decreases, the LV mass reduces (20). However, a high afterload was paradoxically found in ANbC-treated patient (12). The same phenomenon was found in animal models. Matsumura et al. found that DOX caused the cardiac atrophy and induced higher blood pressure after angiotensin II treatment (24). In addition, DOX-treated juvenile mice failed to develop cardiac hypertrophic response to late-onset hypertension induced by angiotensin II, which resulted into higher blood pressure, cardiac output decline, and overt mortality (24). Maayah et al. also reported that DOX treatment led to the impairment of the adaptive hypertrophic response to hypertrophic stimuli (25). Insufficient ventricular mass plus high chronic afterload

contributes to the progressive contractile deficit, decreased cardiac output, and the establishment of cardiomyopathy (18). These may explain why hypertension markedly increased the risk for coronary artery disease, HF, valvular disease, and arrhythmia in aging adult survivors of childhood cancer (26).

The LV mass loss derives from both cell death (27, 28) and cardiomyocyte atrophy (CMA) (11), leads to cardiac atrophy. It should be noted that cardiac atrophy is different from CMA. The term of cardiac atrophy generally defined as an acquired reduction in the size and mass of the heart (29), is usually evaluated by HW, HW/BW ratio, or HW/tibia length (TL) ratio in animal DIC model. A great number of studies have revealed that DOX caused cardiac atrophy, as indicated by the decrease of HW, HW/TL ratio or HW/BW ratio (30–35). However, several studies reported that DOX caused a reduction of HW and BW, did not affect or increase the HW/BW ratio (36–38). It was reported that the delivery of DOX through intraperitoneal route resulted into peritoneal damage, which interfered the food intake and absorption and caused BW loss (39). Therefore, the preserved or increased HW/BW ratio may originate from the greater BW reduction. Therefore, it may be more appropriate to evaluate the cardiac atrophy by HW/TL ratio or HW alone, which is more evident mostly.

Despite numerous studies focusing on the cell death, less attention was paid on the CMA in DIC studies. However, the weight of cardiomyocyte apoptosis in DIC might be overstated (40). Several studies demonstrated that the contribution of cardiomyocyte apoptosis is low in acute DIC model. Willis et al. reported that CMA rather than cell death determines the cardiac atrophy in acute DIC mice model. They sacrificed mice 7 days after injected with DOX (20 mg/kg) and found that there were barely no increase of serum Troponin-I level and TUNEL-stained cell number in DOX treated mice, however, a 44% reduction of cell cross-section area and an obvious cardiac atrophy were detected (11). Little doxorubicin-induced apoptotic effect in acute DIC model was reported by other groups (41–44). However, it was also reported that DOX caused a great amount of apoptotic cardiomyocyte in an acute DIC model (45–47). Maybe apoptosis plays less important role in cardiac atrophy of acute DIC than we thought. While in a chronic DIC model, cardiomyocyte may undergo a hypertrophy response in a compensated manner (48), CMA was also found in a chronic DIC model (49–51). The controversial results will require further research to clarify, and the role of CMA in the DIC model should be evaluated. In a study including 27 women with breast cancer, patients received the cardiac magnetic resonance image exam at 351–700 days after anthracycline therapy (240 mg/m<sup>2</sup>). Ferreira et al. found that the LV mass index in these patients is correlated with intracellular water lifetime ( $\tau_{ic}$ ; a cardiomyocyte size maker) other than with extracellular volume (ECV), indicating that the cardiac atrophy originates from CMA (52). Cell size shrinkage alone accounted for an ~44% reduction in LV mass, while the increased ECV may attenuate the LV mass loss (52). Except for apoptosis, other forms of cell death had been found and demonstrated to participate in DIC (27), the relative contribution of cell death and CMA in DOX-induced cardiac atrophy needs further studies to illustrate.

Here, we aim to emphasize the importance of CMA in cardiac atrophy, summarize the current knowledge of the effect of DOX on CMA, and provide insight into the underlying molecular mechanism of it, finally discuss some approaches that have been identified to protect it.

## MOLECULAR MECHANISM

### Forkhead Box O1 (FOXO1)

Forkhead box O (FOXO) proteins are transcription factors regulating multi physiological and pathological processes included in cardiovascular system. The family contains four members in human, FOXO1, FOXO3, FOXO4, and FOXO6 (53). FOXOs are key regulators in maintaining the muscle mass (54). Depletion of FOXOs has been reported to prevent the muscle loss and weakness through suppressing autophagy-lysosome systems (ALS) and ubiquitin-proteasome systems (UPS) *via* inhibiting the AKT activity (55). Sengupta et al. reported that FOXOs activation may reduce the cardiomyocyte size by promoting autophagy (56). Additionally, Skurk et al. (57) reported that AKT-FOXO3a signaling regulates cardiomyocyte cell size against hypertrophy *via* mediating the expression of atrophy-related genes “atrogenes”. Actually, FOXOs regulates half of the atrogenes by binding their promoters, such as muscle RING finger 1 (MuRF1), muscle atrophy gene-1 (atrogen-1/MAFbx), and Bcl-2 19-kDa interacting protein 3 (Bnip3) (55). Atrogen-1 and MuRF-1 are two members of E3 ubiquitin ligases mastering the ubiquitin-mediated protein degradation (58). Bnip3, an autophagy-related gene, has been reported to regulate CMA in a model of mechanical unloading (59).

It has been reported that high dose (20 mg/kg) of DOX treatment activated FOXO1 phosphorylation at Ser-249 and upregulated nuclear FOXO1 levels, accompanied with the increased expression of its target gene, MuRF1 within 24 h. Pharmacological inhibition of FOXO1 with AS1842856 decreased MuRF1 and prevented DOX-induced CMA and LV mass loss (60). Consistently, Willis et al. reported that DOX treatment resulted into a significant upregulation of MuRF1 and Bnip3, while MuRF1 depletion reversed DOX-induced cardiac atrophy in mice (11). Yamamoto et al. reported that DOX-induced CMA was abrogated by MG-132, a proteasome inhibitor, indicating that the atrophy response is involved in the UPS (61). Wang et al. reported that 3-MA, an autophagy inhibitor, alleviated the DOX-induced CMA *in vitro* and Ghrelin, a multi-functional peptide hormone, attenuated DOX-induced CMA by inhibiting the excessive autophagy (62) (**Figure 1**).

The expression of FOXO1 and its target genes might be induced by DOX in a time- and dose-dependent manner. Low dose (5 mg/kg) of DOX failed to induce MuRF1 expression at 24 h (60). In addition, the mRNA levels of FOXO1 and Atrogen-1 were not upregulated in mice 7 days after injected with 20 mg/kg DOX (11).

In conclusion, DOX triggers catabolic process involving the induction of ALS and UPS *via* activating FOXO1 and its target genes, which contributes to the CMA. However, FOXOs are classified as tumor suppressor genes (63), inhibition of FOXOs may compromise the anti-tumor effect of DOX. Therefore, more

precise and comprehensive studies need to be conducted to figure out if FOXOs inhibition is benefit in DIC therapy in patients with cancer (**Figure 1**).

### Transient Receptor Potential Canonical 3 (TRPC3)-NADPH Oxidase 2 (Nox2) Axis

Transient receptor potential canonical (TRPC) proteins, regulating intracellular  $\text{Ca}^{2+}$ ,  $\text{K}^{+}$ , and  $\text{Na}^{+}$ , are involved in a variety of physiological and pathological processes in cardiovascular system (64). It has been reported that TRPC3 is a risk factor deteriorating the pathological cardiac remodeling (65, 66). TRPC3 was upregulated underlying the DOX-induced hypoxia stress, silence of TRPC3 ameliorated DOX-induced CMA (29). NADPH oxidase 2 (Nox2) is a key regulator accounting for the major reactive oxygen species (ROS) generation in response to cardiac injury. Nox2 knock-out mice exhibited ameliorated CMA and improved the cardiac function against accumulative DOX toxicity, which may be associated with the decrease of NADPH oxidase activity and oxidation (67).

Transient receptor potential canonical 3 (TRPC3) protects Nox2 from proteasome-dependent degradation *via* interacting with it at the specific C-terminal sites and promotes its activation by regulating  $\text{Ca}^{2+}$  entry (65). The functional interaction of TRPC3 and Nox2 is required for DOX-induced CMA, as the supplement of the TRPC3-C terminal fragment peptide, which disrupted the TRPC3-Nox2 complex without affecting the TRPC3 channel activity, attenuated DOX-induced CMA (29). Further, pharmacological inhibition of TRPC3-Nox2 complex by pyrazole-3 (Pyr3) abrogated DOX-induced CMA and ameliorated cardiotoxicity (29).

However, the downstream mechanism of TRPC3-Nox2 in DOX-induced CMA remains poorly known. It was reported that the mitochondrial dysfunction promoted muscle disuse atrophy by increasing oxidation stress, impairing  $\text{Ca}^{2+}$  handling, and activating associated cellular degradation processes (68, 69). TRPC3 was found to translocate to the mitochondria to mediate mitochondrial  $\text{Ca}^{2+}$  homeostasis and regulate the mitochondrial function (70). The number of evidence has revealed that the TRPC3-induced ROS emission and mitochondrial dysfunction participate in cardiac remodeling (65, 66, 71).  $\text{Ca}^{2+}$  overload is one of the major causes of DIC, Chen et al. reported that the upregulation of TRPC3 and TRPC6 contributed to the  $\text{Ca}^{2+}$  overload in DIC (72). Calmodulin is a ubiquitously expressed calcium binding protein which plays a key role in transducing intracellular calcium signal (73). Trifluoperazine, a strong calmodulin antagonist, was found to alleviate myofibril degeneration and cardiac atrophy induced by DOX (74). Calpains are  $\text{Ca}^{2+}$ -activated neutral cysteine proteases and comprise two major molecules, calpain-1 and calpain-2 (75). Min et al. reported that DOX-induced skeleton and cardiac atrophy requiring the increased mitochondrial emission of ROS and calpain activation (76). Therefore, it can be speculated that DOX might induce CMA through TRPC3-Nox2 axis by disrupting the mitochondrial function, increasing  $\text{Ca}^{2+}$  entry, and activating the  $\text{Ca}^{2+}$ -associated calpain protein degradation system (**Figure 1**).

**FIGURE 1 |** The related molecular mechanism of doxorubicin (DOX)-induced cardiomyocyte atrophy (CMA). ALS, autophagy-lysosome systems; atrogin-1/MAFbx, muscle atrophy gene-1; Bnip3, Bcl-2 19-kDa interacting protein 3; DOX, doxorubicin; FOXO1, forkhead box O1; IGF-1, insulin-like growth factor; IGF-1R, IGF-1 receptor; MuRF1, muscle RING finger 1; mTOR, mammalian target of rapamycin; Nox2, NADPH oxidase 2; PI3K, phosphoinositide 3-kinase; p38 MAPK, p38 mitogen-activated protein kinase; TRPC3, transient receptor potential canonical 3; UPS, ubiquitin-proteasome systems.

## Phosphoinositide 3-Kinase (PI3K) Insulin-Like Growth Factor 1 (IGF-1) and PI3K

Insulin-like growth factor 1 (IGF-1), a key growth factor controlling both anabolic and catabolic pathways, plays a critical role in modulating the muscle size and function (76). IGF-1 binding to IGF-1 receptor (IGF-1R) leads to increased phosphorylation of insulin receptor substrate-1 (IRS-1), which recruits phosphoinositide 3-kinase (PI3K) and activates downstream the AKT signaling pathway (77). Besides, IGF binding protein (IGFBP) regulated IGF-1 activity by keeping it away from IGF-1R (78). DOX was reported to impair IGF-1R and upregulate IGFBP *via* p53 activation in H9C2 cells (79, 80). Restoration of IGF-1R-PI3K-AKT signaling pathway increased the cell survival ability against DIC (79, 80). Apart from that, exogenous IGF-1 (81) or insulin (82) were reported to alleviated DOX-induced cardiomyocyte apoptosis *via* stimulating PI3K-AKT. Interestingly, Mousa et al. discovered that the co-treatment of human umbilical cord blood mesenchymal stem cells

(hUCB-MSCs) and carvedilol alleviated DOX-induced decrease of cardiac muscle fiber diameter, which is accompanied with the elevation of IGF-1, GATA-binding protein 4 (GATA-4), and vascular endothelial growth factor (VEGF) (83). Studies have uncovered that IGF-1 is a pro-hypertrophic inducer in cardiomyocyte (84, 85). Further, exogenous IGF-1 reversed cisplatin-induced skeleton muscle atrophy through inhibiting PI3K-AKT-FOXO mediated UPS (86). Overexpression of IGF-1 was also found to ameliorate cardiac atrophy in spinal muscular atrophy mice (87). However, whether IGF-1/IGF-1R have the potent to rescue CMA induced by DOX remains unknown (Figure 1).

## PI3K and AKT

The PI3K-AKT signaling pathway plays a vital role in regulating the muscle hypertrophy and atrophy response (77). Studies have revealed that DOX inhibited PI3K-AKT activity both *in vivo* and *in vitro* (79, 88–90). PI3K, a lipid kinase family transducing

receptor tyrosine kinase signaling, is aberrantly upregulated in human cancers frequently (91). Though targeting PI3K is effective in cancer therapy, inadvertently increases its side effect on the heart (92). PI3K is a key node in growth factor signaling as well as a modulator in heart muscle mass and contractility (93). Brent et al. found that specific inhibition of PI3K $\alpha$  by BYL719 decreased the cross-sectional area of cardiomyocyte and induced cardiac atrophy (94). The use of PI3K inhibitor enhanced the anti-tumor effect of chemotherapy drugs, such as DOX (95, 96), while cotreatment of DOX and BYL719 aggravated CMA and cardiotoxicity compared with DOX alone (94). In addition, several studies shed the relationship of PI3K-AKT and cardiac atrophy as well. For example, Chen et al. found that total flavonoids stimulated PI3K-AKT and attenuated DOX-induced HW loss, while inhibition of PI3K-AKT abrogated the protection of total flavonoids against DIC (97). Meeran et al. revealed that nerolidol, a sesquiterpene from the essential oils of aromatic plants, alleviated DOX-induced cardiac atrophy possibly *via* the PI3K-AKT pathway (88). Intriguingly, both upregulation and downregulation of PI3K-AKT triggered by DOX has been reported (98, 99). The discrepancy may be explained by different DIC models and detected time. Interestingly, Cao et al. found that AKT activity was induced by DOX in the beginning, while this was suppressed in the long term (100). In addition, it was reported that PI3K $\gamma$  inhibition ameliorated DOX-induced CMA and cardiotoxicity as well as reduced tumor growth (101). Therefore, the role of PI3K-AKT in DIC requires deeper research to clarify and subunit specific inhibition of PI3K might be a promising idea.

Phosphoinositide 3-kinase-AKT activation promotes FOXOs to transport from nucleus to cytoplasm, where FOXOs are sequestered by 14-3-3 proteins and stay inactive (102). Several studies have revealed that the inhibition of PI3K-AKT signaling pathway promoted muscle atrophy *via* FOXOs-mediated activation of UPS (103–105). Moreover, Spurthi et al. reported that toll-like receptor 2 deficiency suppressed PI3K-AKT and activated FOXO1-atrogin-1/MuRF1, which resulted into cardiac atrophy in aging mice (106). Ni et al. found that angiotensin II induced cardiac hypertrophy *via* PI3K-AKT-FOXO pathway (107). Therefore, DOX-induced CMA may be associated with PI3K-AKT-FOXO pathway, which need further exploration. Worth to mention, Yamamoto et al. reported that DOX treatment induced a rapid increase of atrogin-1 mRNA expression *via* activation of p38 mitogen-activated protein kinase (MAPK) pathway without modulating the AKT-FOXO pathway (61).

Mammalian target of rapamycin (mTOR), acts as a serine/threonine kinase, plays an important role in regulating the protein synthesis and modulating autophagy by phosphorylating p70S6K and 4E-BP and Ulk-1, respectively (108, 109). The activity of mTOR regulates the cell growth and organ size (110). The AKT-mTOR axis has been reported to be involved in cardiac hypertrophy during volume overload (111). Further, the PI3K-AKT-mTOR signaling pathway has been found to participate in the DOX-induced skeleton muscle atrophy and cancer cachexia-related cardiac atrophy (112, 113). DOX was reported to impair AKT-mTOR axis by several research (82, 114–117). As reported,  $\beta$ 2-agonist formoterol was reported

to decrease protein degradation partially through inhibiting PI3K-AKT-mTOR mediated ALS, which prevented the muscle mass loss in fasted mice (118). Apart from that, the activation of PI3K-AKT signaling pathway prevented muscle atrophy *via* mTOR-mediated inhibition of ALS (119, 120). Wang et al. found that ghrelin ameliorated DOX-induced CMA by inhibiting excess autophagy *via* stimulating mTOR (62). Additionally, Hullin et al. revealed that enalapril protected against cardiotoxicity and CMA caused by DOX possibly through activating the PI3K-AKT-mTOR pathway (50). To sum up, DOX might cause CMA *via* inhibiting protein synthesis and activating ALS by suppressing the PI3K-AKT-mTOR pathway (Figure 1).

### PI3K and p38 MAPK

The p38 MAPK family, which responses to the stress stimuli, plays an important role in cardiac development and function (121). The *in vivo* and *in vitro* evidence has shown that DOX activated the p38 MAPK pathway, which contributed to the DIC (89, 100, 122, 123). McLean et al. reported that suppression of PI3K $\alpha$  with BYL719 or DOX activated p38 MAPK (94). The stimulation of p38 MAPK is correlative with the muscle wasting. Puigserver et al. found that p38 MAPK activation led to mitochondrial uncoupling and energy expenditure in muscle wasting (124). In addition, Fukawa et al. reported that cancer-secreted inflammatory factors resulted into the excessive fatty acid oxidation and the activation of p38 MAPK, which led to muscle atrophy (125). Several studies have revealed that the activation of p38 MAPK was responsible for DOX-induced CMA. Szeto-Schiller 31 (SS31), an antioxidant peptide, inhibited p38 MAPK phosphorylation and CMA induced by DOX (122). Diosgenin, a steroidal saponin of Dioscorea opposite, alleviated DOX-induced HW and HW/BW ratio reduction possibly *via* suppressing p38 MAPK (123). Further, therapeutic inhibition of p38 MAPK signaling mitigated DOX-induced CMA (94). However, the mechanism that downstream the p38 MAPK in DOX-induced CMA is beyond well established. It was reported that p38 MAPK activation resulted into the upregulation of atrogin-1 and the activation of catabolic process in cancer-induced muscle wasting (126). Pharmacological inhibition of p38 MAPK blunted DOX-induced atrogin-1 upregulation in cardiomyocytes and overexpression of atrogin-1 resulted into CMA (61). Besides, Odeh et al. reported that compromised p38 MAPK activity prevented the denervation-induced muscle atrophy through inhibiting UPS, decreasing oxidation stress, and increased clearance of damaged mitochondria (127). Ding et al. found that Activin A induced skeleton muscle atrophy *via* p38 mediated activation of UPS and autophagy, shown by the upregulation of atrogin-1 and LC3II (128). Therefore, DOX may induce CMA by activating catabolic process through PI3K-p38-atrogin-1 signaling pathway (Figure 1).

## THERAPY STRATEGIES

### Exercise

Appropriate exercise has been demonstrated to be beneficial for alleviating the muscle atrophy and improving the muscle strength (129). Wang et al. reported that moderate aerobic

exercise decreased DOX exposure in cardiac tissue without altering the microvascular density (130). They found that moderate aerobic exercise during DOX treatment counteracted heart mass loss and cardiac function decline in juvenile tumor-bearing nude mice, while failed to preserve the cardiac function when exercise started after the closure of chemotherapy (130). Gomes-Santos et al. (131) found that aerobic exercise training prevented CMA, ameliorated cardiac atrophy, and attenuated exercise intolerance in mice developed with chronic DIC. While the LVEF reduction and fibrosis were not mitigated by it. Several studies have revealed the molecular mechanism underlying the effect of exercise in ameliorating DOX-induced CMA. Activation of TRPC3-Nox2 pathway contributes to the DOX-induced CMA, it was reported that voluntary exercise downregulated TRPC3 and Nox2 in a posttranslational manner (29). Further, it was reported that exercise upregulated IGF-1 mRNA expression (132) and activated PI3K-AKT impaired by DOX (133). Additionally, Kavazis et al. reported that the short-term endurance exercise training attenuated mRNA expression of some negative regulators of cardiac mass, such as FOXO1, MuRF1, myostatin but not atrogin-1, and Bnip3, which was probably associated with the activation of AMPK/PGC-1 $\alpha$  pathway (134).

### Non-Coding RNA (ncRNA)

Non-coding RNA (ncRNA), such as microRNA, small interference RNA (siRNA), long non-coding RNA (lncRNA), and circular RNA (cirRNA), plays an important role in regulating the cardiovascular system (135). Hu et al. reported that DOX treatment resulted into miR-200a downregulation both *in vivo* and *in vitro*, overexpression of miR-200a alleviated DOX-induced cardiac atrophy and cardiac dysfunction *via* nuclear factor (erythroid-derived 2)-like 2 (Nrf2) activation (136). Li et al. (137) also found that DOX caused elevation of miR-451 expression and miR-451 inhibition prevented the whole body wasting and cardiac atrophy and alleviated cardiotoxicity through AMPK signaling pathway in DIC mice. Moreover, Gupta et al. found that miR-212/132, a pro-hypertrophic cluster, ameliorated DOX-induced CMA and improved cardiac function by inhibiting downstream fat storage-inducing transmembrane protein 2 (Fitm2) (138). In addition, they found that Quaking, an RNA-binding protein, exerted cardiac protective effect against DOX-induced CMA and cardiotoxicity *via* mediating cardiac cirRNAs derived from Titin (Ttn), Formin homology 2 domain containing 3 (Fhod3), and Striatin calmodulin-binding protein 3 (Strn3) (139). It seems that interfering with ncRNAs may provide a new strategy in reversing the DOX-induced CMA, however, the related studies remain limited.

### Hormones and Growth Factors

Growing evidence has demonstrated that part of endogenous hormones and growth factors have protective effect in cardiovascular diseases (140–143). Vascular endothelial growth factor-B (VEGF-B), one of the five known members of VEGF that regulate endothelial function (144), has been demonstrated to show potent in promoting coronary arteriogenesis and physiological cardiac hypertrophy (145). Räsänen et al. reported

that overexpression of VEGF-B reversed CMA and cardiac mass loss through protecting endothelial in DOX-treated mice without compromising the anti-tumor effect of DOX (146). Li et al. (44) reported that exogenous supplementation of erythropoietin ameliorated DOX-induced CMA and cardiac dysfunction. The same team found that the atrophic response was attenuated by giving granulocyte colony-stimulating factor (G-CSF) in acute DIC mice in their following study (43). Interestingly, Esaki et al. reported that artificial upregulation of hepatocyte growth factor (HGF) at 2 weeks after the establishment of acute DIC model mitigated DOX-induced CMA and cardiac dysfunction (42). The related mechanism underlies the anti-atrophic effect of erythropoietin, G-CSF, and HGF might be similar, which was related to the activation of extracellular signal-regulated kinase (ERK) as well as the restoration of the expression of GATA-4 and its downstream 3 sarcomeric proteins, myosin heavy chain, troponin I, and desmin (42–44). GATA-4, a member of the GATA family of zinc finger transcription factors, is a major transcription factor regulating sarcomeric genes (147). DOX treatment caused a decrease in the level of GATA-4 DNA-binding activity as a result of downregulation of GATA-4 (148), which downregulated the sarcomeric proteins, and resulted into the degeneration of myofibrils in response to DOX.

### Polyphenolic Compounds

The plant-derived polyphenolic compounds exert powerful antioxidant activity and have showed their beneficial effects in cardiovascular disease, such as DIC (149). The polyphenolic compounds can be classified as flavonoids, stilbenes, phenolic acids, and lignans based on the molecular structure (150). Rutin, a polyphenolic flavonoid, prevented DOX-induced cardiac atrophy and dysfunction *via* inhibiting excessive autophagy, reducing apoptosis, and restoring AKT activity (151). Isorhapontigenin, a new derivative of stilbene, alleviated CMA and cardiac atrophy caused by DOX, which is associated with the upregulation of yes-associated protein 1 expression (31). Resveratrol (3,5,4'-trihydroxy-trans-stilbene, RES), a natural polyphenol which can be found mainly in grapes, red wine, soy, and peanuts, has been well studied in DIC protection (152). Earlier, Zhang et al. found that RES prevented DOX-induced HW, BW, HW/BW ratio reduction, and cardiotoxicity *via* sirtuin 1 (SIRT1)-p53 pathway (153). Furthermore, Arafa et al. revealed that RES was capable of alleviating cardiac atrophy caused by DOX (154). Several studies have implicated the possible molecular mechanism of the protection of RES on DOX-induced cardiac atrophy. It was reported that RES inhibited DOX-induced catabolic process as indicated by the downregulation of MuRF1 and ubiquitin-specific protease 7 (USP7) *via* increasing the deacetylase activity of SIRT1 in young mice (155). RES was reported to suppress DOX-induced p38 MAPK activation (24, 156) and restore VEGF-B and AKT impaired by DOX (157). Recently, Maayah et al. reported that RES ameliorated DOX-induced cardiac atrophy and cardiotoxicity through inhibiting nucleotide-binding domain-like receptor protein-3 (NLRP3) and systemic inflammation in juvenile mice (25). Interestingly, they found that RES restored DOX-induced deficiency of compensated

hypertrophic response to the late-onset hypertension, as indicated by the alleviated CMA and increased heart wall thickness (25). Of note, some polyphenolic compounds have shown the effectiveness against cancer cells both *in vivo* and *in vitro* (158).

## Clinical Drugs

The advantage of clinical drugs is the proved relative safety and the convenience for application. Here, we presented several studies about the protective effect of clinical drugs in DOX-induced CMA. Although the results of clinical study showed that only 11% patients showed complete recovery from DIC receiving conventional HF drugs (10), which may be associated with the underlying mechanism of DIC is cardiac atrophy rather than pathological hypertrophy. Losartan, a clinical used AT1 receptor antagonist, exerted cardioprotective effect against DOX-induced CMA possibly by inhibiting the Nox2 activity (67). Controversial studies about the effect of eplerenone on DIC were reported (50, 159). Enalapril, an angiotensin converting enzyme inhibitor (ACEI), attenuated DOX-induced CMA possibly *via* stimulating the PI3K-AKT-mTOR pathway and maintaining the normal levels of connective tissue growth factor (50). So, it reminds us that it is possible for some specific group population to benefit from the conventional HF drugs in DIC therapy? Oral supplementation of folic acid prevented myofibrils disruption, ameliorated DOX-induced CMA, and improved cardiac function (160). Of note, Durham et al. reported that upregulation of high-density lipoprotein (HDL) by overexpressing apolipoprotein A1 abrogated DOX-induced CMA in mice, which was required for the high-affinity HDL receptor, scavenger receptor class B type 1 (49). This study implicates that a lipid-lowering therapy may be beneficial for DOX-induced CMA.

The phosphodiesterase 5 (PDE5) inhibitors, such as tadalafil, sildenafil, and vardenafil, have been demonstrated to show protection in cardiovascular system (161). Koka et al. revealed that tadalafil, a long-acting selective inhibitor of cGMP-specific PDE5, improved cardiac function, reduced oxidation stress, attenuated apoptosis, and prevented cardiac atrophy in DIC mice (162). Prysyazhna et al. found that tadalafil protected against DOX-induced LV mass loss *via* attenuating protein kinase G I $\alpha$ oxidation (163). Moreover, Jin et al. reported that tadalafil ameliorated the downregulation of 3 sarcomeric proteins, myosin heavy chain, troponin I, desmin, and alleviated CMA caused by DOX in mice (41). Another PDE5 inhibitor, sildenafil, has been verified to attenuate cardiac dysfunction, apoptosis, mitochondrial damage, and myofibrillar disarray induced by DOX (164). Multiple studies have reported that the administration of PDE5 inhibitors did not affect the anticancer effect but enhanced chemotherapeutic efficacy of DOX in animal tumor models (165–168). However, Poklepovic et al. found that sildenafil was safe, but did not show cardiac protection following DOX treatment in a small randomized clinical trial (169). The effect of sildenafil in DIC will require deeper research to verify. Worth to mention, several studies have shed light into the cardiac protective effect of other PDE inhibitors against DIC. Nishiyama et al. found that ibudilast, a PDE4 inhibitor already used in clinic,

exerted cardioprotective effect against DOX-induced CMA by interfering the TRPC3-Nox2 complex without affecting the TRPC3 activity (170). Recently, Chen et al. reported that PDE10A deficiency ameliorated DOX-induced CMA and cardiotoxicity *via* cGMP and cAMP, and PDE10A inhibition antagonized tumor growth (171). Inspiringly, the safety of several PDE10A inhibitors have been demonstrated in phase I clinical trial (171). Zhang et al. revealed that PDE1C deficiency or suppression of ameliorated DOX-induced cardiac atrophy and improved cardiac function *via* adenosine A2 receptor stimulation (172). Cilostazol, a potent PDE3 inhibitor, also alleviated HW loss in DIC (173).

## DISCUSSION

In this review, we pointed out the importance of CMA in DIC and then, summarized recent advances in the molecular mechanism and the promising therapy strategies of DOX-induced CMA. Here, we paid more attention to the studies involving DOX-induced CMA, but not merely cardiac atrophy. Cardiac atrophy is a common finding and a major cause in the DIC. The weight of CMA in cardiac atrophy might be greater than we thought before. In addition, the reversibility of DIC also supports it (174). We are not going to say that we should downgrade the role of cell death yet. Although several studies have reported that little apoptotic effect was found in acute DIC models, the part of cardiomyocyte necrosis was not evaluated (11, 42–44). The apoptotic rate may be underestimated due to the secondary necrosis (175, 176). So, the relative contribution of CMA and cell death in DOX-induced cardiac atrophy is worth to elucidate in the future study. Inhibiting cellular degradation processes and promoting synthesis processes might be the key idea in preventing the DOX-induced CMA. The DOX-induced CMA is a degenerated process, which explains the protective effect of pro-growth therapy, such as exercise and supplementation of growth factors. Pathological hypertrophy is found in multi cardiovascular diseases; however, appropriate hypertrophy can be helpful for alleviating the DOX-induced CMA as proved by Gupta et al. (138). Considering that the cardiac regeneration technology is still far from application in clinic nowadays (177), reversing CMA serves an alternative and promising strategy in DIC therapy.

## AUTHOR CONTRIBUTIONS

D-SC collected the literature and wrote the manuscript. JY and P-ZY conceived the idea and supervised the manuscript. All authors agree to be accountable for the content of the work. All authors contributed to the article and approved the submitted version.

**Objective:** Many studies have reported that microRNAs (miRs) are involved in the regulation of doxorubicin (DOX)-induced cardiotoxicity. MiR-194-5p has been reported significantly upregulated in patients with myocardial infarction; however, its role in myocardial diseases is still unclear. Various stimuluses can trigger the endoplasmic reticulum (ER) stress and it may activate the apoptosis signals eventually. This study aims to explore the regulatory role of miR-194-5p in DOX-induced ER stress and cardiomyocyte apoptosis.

**Methods:** H9c2 was treated with 2  $\mu$ M DOX to induce apoptosis, which is to stimulate the DOX-induced cardiotoxicity model. The expression of miR-194-5p was detected by quantitative real-time PCR (qRT-PCR); the interaction between miR-194-5p and P21-activated kinase 2 (PAK2) was tested by dual luciferase reporter assay; terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) assay and caspase-3/7 activity were used to assess apoptosis; trypan blue staining was applied to measure cell death; Western blotting was performed to detect protein expressions; and ER-related factors splicing X-box binding protein 1 (XBP1s) was detected by polyacrylamide gel electrophoresis and immunofluorescence to verify the activation of ER stress.

**Results:** MiR-194-5p was upregulated in cardiomyocytes and mouse heart tissue with DOX treatment, while the protein level of PAK2 was downregulated. PAK2 was predicted as the target of miR-194-5p; hence, dual luciferase reporter assay indicated that miR-194-5p directly interacted with PAK2 and inhibited its expression. TUNEL assay, caspase-3/7 activity test, and trypan blue stain results showed that either inhibition of miR-194-5p or overexpression of PAK2 reduced DOX-induced cardiomyocyte apoptosis. Silencing of miR-194-5p also improved DOX-induced cardiac dysfunction. In addition, DOX could induce ER stress in H9c2, which led to XBP1 and caspase-12 activation. The expression level of XBP1s with DOX treatment increased first then decreased. Overexpression of XBP1s suppressed DOX-induced caspase-3/7 activity elevation as well as the expression of cleaved caspase-12, which protected cardiomyocyte from apoptosis. Additionally, the activation of XBP1s was regulated by miR-194-5p and PAK2.

**Conclusion:** Our findings revealed that silencing miR-194-5p could alleviate DOX-induced cardiotoxicity *via* PAK2 and XBP1s *in vitro* and *in vivo*. Thus, the novel miR-194-5p/PAK2/XBP1s axis might be the potential prevention/treatment targets for cancer patients receiving DOX treatment.

**Keywords:** doxorubicin, cardiotoxicity, miR-194-5p, ER stress, apoptosis

## INTRODUCTION

Doxorubicin (DOX) is a broad-spectrum antitumor drug that can be used to treat a variety of cancers. However, the clinical utility of DOX is confined due to its cumulative cardiotoxicity (1, 2). In the past decades, the mechanisms of DOX-induced cardiotoxicity have been extensively studied, mainly including accumulation of reactive oxygen species (ROS), mitochondrial dysfunction, endoplasmic reticulum (ER) stress, and disturbance of calcium homeostasis (3–8). However, the exact mechanism underlying DOX cardiotoxicity has not been fully discovered. In addition, the aberrant apoptosis caused cardiomyocytes number decrease is the predominant cellular event in DOX-induced cardiomyopathy, which was confirmed by morphological changes and terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) assay (9–11). Therefore, to further explore the mechanisms of DOX-induced cardiomyocytes apoptosis will help minimize its adverse effects and benefit the clinical application.

MicroRNA (miR, miRNA) is a type of non-coding RNA with a length of approximately 22 nucleotides, and they exert their functions by degrading target mRNAs and inhibiting protein expressions, therefore, participate in various biological processes, such as proliferation, migration, differentiation, and cell death (12, 13). Many studies have reported that miRNAs play important roles in the DOX-induced cardiotoxicity (14–17). Recently, it has been reported that miR-194 is upregulated in the serum of patients with myocardial infarction and is closely correlated with impaired cardiac function (18). In addition, the expression level of circulating exosomal miR-194 was also upregulated in patients with obese cardiomyopathy, which was closely related to the mitochondrial activity and cardiac function (19). However, the role of miR-194 in DOX-induced cardiotoxicity is unclear.

P21-activated kinase 2 (PAK2), a Rac1/Cdc42 activated signaling effector, belongs to the PAK family of serine/threonine kinases (20). The antiapoptotic effect of PAK2 has been demonstrated in multiple cancer studies (21–23). Recently, PAK2 has been reported to exert cardioprotective role by improving ER function through the inositol-requiring enzyme 1 (IRE1)/X-box binding protein 1 (XBP1)-dependent pathway (24). In cardiomyocytes hypoxia and reoxygenation model, the decrease of PAK2 is associated with ER stress, oxidative stress, calcium overload, caspase-12 (cas-12) activation, and apoptosis (25). Activation of 5' AMP-activated protein kinase (AMPK)-p21-activated kinase 2 (PAK2) signaling attenuated ER stress and myocardial apoptosis induced by ischemia/reperfusion injury (26). Nonetheless, the role of PAK2 in DOX-induced cardiotoxicity has not been elucidated.

It has been reported that ER stress is involved in DOX-induced cardiotoxicity (27, 28). When the ER is under stress that cannot afford the excessive unfolded proteins to be processed, the unfolded protein response (UPR) is triggered to restore the ER homeostasis (29, 30). Severe or prolonged ER stress will switch the cells from adaptive phase to apoptosis. XBP1 is the key transcription factor in the IRE pathway in response to UPR. During UPR, XBP1 is activated and its mRNA is cleaved to form the splicing XBP1 (XBP1s) (31). XBP1s can bind to ER stress response elements in promoters of many UPR target genes, therefore help to fold and degrade proteins, promoting ER adaption and cytoprotection (32, 33). Studies reported that XBP1s also plays a key role in cardiovascular disease. A recent study showed that XBP1s modulates vascular endothelial growth factor-mediated cardiac angiogenesis and contributes to the development of adaptive hypertrophy (34). Similarly, in the transgenic mouse model, overexpression of XBP1s showed protective effect on reperfusion injury (35). However, the role of XBP1 in DOX-induced cardiotoxicity needs further study.

In this study, we reported that the expression of miR-194-5p increased in DOX-induced cardiomyocytes and mouse heart tissue and was involved in the regulation of DOX-induced cardiotoxicity by targeting PAK2. Inhibition of miR-194-5p attenuated DOX-induced apoptosis, and PAK2 showed important role in maintaining endoplasmic reticulum homeostasis to exert cardioprotective effects *via* the key transcription factor-XBP1. The present results revealed the regulatory role of miR-194-5p/PAK2/XBP1s axis in DOX-induced cardiotoxicity and provided a theoretical basis for the development of therapeutic targets.

## MATERIALS AND METHODS

### Animal Experiments

A 8-week old male C57BL/6J mice were randomly divided into the 4 groups: the control group, the DOX treatment group, the DOX and antagomir negative control group, and the DOX and miR-194-5p antagomir group. All the mice were housed on a 12-h light/12-h dark cycle in a pathogen-free environment and allowed *ad libitum* access to food and water. Adenovirus-harbored miR-194-5p antagomir ( $5 \times 10^{10}$  vector genomes) was synthesized by Hanbio Corporation Ltd. (Shanghai, China). The animals in the antagomir group and its negative control (NC) group were injected *via* tail vein with miR-194-5p antagomir 50  $\mu$ l or same dosage of antagomir NC. On day 7, the experimental groups (DOX group, DOX + antagomir NC group, and DOX + miR-194-5p antagomir group) were intraperitoneally injected with DOX hydrochloride

15 mg/kg once. Same dose of normal saline was injected to the control group. Cardiac function was tested 1 week after DOX administration and mice were euthanized after *in vivo* evaluations of cardiac function. Then, hearts were rapidly excised and immediately cut into two parts. One part was snap-frozen in liquid nitrogen and the remaining part was fixed in 4% polyformaldehyde solution and embedded in paraffin. All the procedures involving animals were reviewed and approved by the Institutional Animal Care and Use Committee of Qingdao University Medical College.

## Cell Culture and Treatment

H9c2 cells (rat cardiomyocytes) were purchased from the Shanghai Institutes for Biological Sciences (Shanghai, China), which were cultured in Dulbecco's Modified Eagle's Medium (DMEM) (Gibco; Thermo Fisher Scientific, Waltham, MA, United States) supplemented with 10% fetal bovine serum (FBS), 100 U/ml penicillin, 100 µg/ml streptomycin, and 110 mg/l sodium pyruvate at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub>. The cells were treated with 2 µM or 0.2 µM DOX (Aladdin, Shanghai, China) at the indicated times.

## Cell Transfection

H9c2 cells were transfected with the Lipofectamine 3000 Transfection Reagent when they reached approximately 70% confluence for 24 h according to the manufacturer's instructions. PAK2 and XBP1s were cloned into the pcDNA3.1 expression and synthesized by Tsingke (Beijing, China). The empty vector of pcDNA3.1 and scramble control were used as negative controls for overexpression and small interfering RNA (siRNA), respectively. MiR-mimic, miR-inhibitor, and si\_PAK2 were purchased from Shanghai GenePharma (Shanghai, China). Their sequences are shown in **Table 1**.

## Quantitative Real-Time PCR

Total RNA obtained from the H9c2 cells or left ventricle tissue was extracted using Trizol reagent. RNA was reverse transcribed with HiScript III RT SuperMix for qPCR (+ gDNA Wiper) reverse transcription kit (Vazyme, Nanjing, China) for mRNA levels testing. Stem-loop quantitative real-time PCR (qRT-PCR) for mature miRNAs was performed as previously described (36) with miRNA 1st Strand cDNA Synthesis Kit (by stem-loop) (Vazyme, Nanjing, China) for miRNA levels

**TABLE 2 |** Real-time quantitative PCR (qRT-PCR) primers used in this study.

Gene	Sequence
U6	F: ATTGGAACGATACAGAGAAGATT R: GGAACGCTTCACGAATTG
miR-194-5p	F: CGCGTGTAACAGCAACTCCA R: AGTGCAGGGTCCGAGGTATT
GAPDH	F: GCCCATCACCATCTTCCAGGAG R: GAAGGGGCGGAGATGATGAC
XBP1s	F: TGAGAACCAGGAGTTAAG R: CCTGCACCTGCTGCGGAC

testing. The miR-194-5p stem-loop primer sequence: 5'-GT CGTATCCAGTGCAGGGTCCGAGGTATTCGCACTGGATAC GACTCCACA-3'. According to the manufacturer's instructions, the cDNA was mixed with the corresponding fluorescent dye SYBR, and the test was carried out in the CFX96 real-time PCR system (Bio-Rad, Hercules, CA, United States). The results were put into the  $2^{-\Delta\Delta CT}$  formula for calculation. MiR-194-5p expression was normalized to that of U6, while XBP1s mRNA level was normalized to that of glyceraldehyde 3-phosphate dehydrogenase (GAPDH). The primers are shown in **Table 2**.

## Cell Apoptosis Assay

The sterile slides were placed in the 24-well plate and then the H9c2 cells were planted on top of the slides. After transfection and treatment, 4% paraformaldehyde added to fix the cells for at least 1 h in room temperature. Cell apoptosis was characterized *via* a TUNEL assay using the TUNEL Apoptosis Detection Kit (YEASEN, Shanghai, China) according to the manufacturer's instructions. The samples were mounted with mounting medium containing 4',6'-diamidino-2-phenylindole (DAPI) (Vector Laboratories, Burlingame, CA, United States) to stain nuclei. The stained-glass slides were observed and photographed under a fluorescence microscope. The percentage of the apoptotic nuclei was calculated by the number of apoptotic cells/the number of total nuclei. We randomly measured 150 cells from each experiment to calculate the apoptotic rate. Caspase-3/7 activity assay was performed using the Caspase 3/7 Activity Assay Kit (Meilunbio, Dalian, China) according to the manufacturer's instructions. Masson's trichrome staining was performed using the staining kit (Solarbio, Beijing, China) following the manufacturer's instructions.

## Trypan Blue Stain

Cell death rate was measured by trypan blue stain (Solarbio, Beijing, China). The supernatant and adherent cells were collected. The cell was prepared and stained by trypan blue according to the manufacturer's instructions. The percentage of the cell death was calculated by the number of trypan blue positive cells/the number of total cells, which were counted under the microscope.

## Western Blot Analysis

Total protein was extracted from H9c2 cells or mouse left ventricle tissue by the radio immunoprecipitation assay

**TABLE 1 |** The sequences of synthesized mimic, inhibitor, small-interfering RNA (siRNA).

Gene	Sequence
miR-194-5p mimic	F: UGUUACAGCAACUCCAUGUGGA R: CACAUGGAGUUGCUGUUAUUAU

Negative control	5'-CAGUACUUUUGUGUAGUACAA-3'
Si_PAK2	5'-GGGAUUGGAAGGCUCAGUUTT-3'
Scramble control	5'-UUCUCCGAACGUGUCACGUTT-3'

(RIPA) Lysis Buffer (Solarbio, Beijing, China) according to the manufacturer's instructions. Proteins were separated by electrophoresis on the sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) (10–12% polyacrylamide gels) and then transferred to polyvinylidene fluoride (PVDF) membranes. Subsequently, the PVDF membranes were blocked in 5% non-fat milk for 2 h and then incubated overnight at 4°C with anti-PAK2 (1:1,000, Cell Signaling Technology, Danvers, MA, United States), or anti-XBP1s (1:1,000, Cell Signaling Technology, Danvers, MA, United States), or anti- $\beta$ -actin (1:2,000, Santa Cruz Biotechnology, Dallas, TX, United States), or anti-GAPDH (1:100,000, ABclonal, Wuhan, China), or anti-cas-12 (1:2,000, Abcam, United States) primary antibodies after washing with TBS-Tween 20 (TBST) three times, 10 min each time. Horseradish peroxidase (HRP)-conjugated secondary antibodies were incubated at room temperature for 1 h, then washed with TBST three times, 10 min each time. Membranes were visualized using enhanced chemiluminescence. Protein expression was quantified using ImageJ, and  $\beta$ -actin or GAPDH was used as the internal control.

### Dual-Luciferase Reporter Gene Assay

The wild-type (WT) and mutated-type (MT) PAK2 fragments of the miR-194-5p binding region were, respectively, inserted into the pGL3 vector immediately downstream of the stop codon of the luciferase gene, to synthesize the reporter gene plasmid (Tsingke, Beijing, China). A luciferase activity assay was performed as described previously (37). Briefly, phRL-TK reporter plasmid and miR-194-5p mimic (or mimic-NC) were cotransfected into HEK-293 cells, which were seeded in 48-well plates. The cells were collected and lysed after 24 h, then the firefly and Renilla luciferase activities were detected by the Dual-Luciferase Reporter Assay System (Promega, Madison, WI, United States). Firefly luciferase activities were normalized to Renilla luciferase activity.

### Polymerase Chain Reaction Product Polyacrylamide Gel Electrophoresis

The extracted RNA was first reverse transcribed into cDNA with HiScript III RT SuperMix for qPCR (+ gDNA wiper) (Vazyme, Nanjing, China). The cDNA was amplified by PCR with Gold Mix rapid PCR enzyme (Tsingke, Beijing, China). About 10% of polyacrylamide gel (per 10 ml: 30% acrylamide 3.33 ml, 10X TBE 1 ml, ddH<sub>2</sub>O 5.614 ml, N,N,N',N'-Tetramethylethylenediamine (TEMED) 5  $\mu$ l, 10% ammonium persulfate (APS) 50  $\mu$ l) were prepared. Electrophoresis was performed in 1  $\times$  TBE solution and the PCR products were separated. Then gel was stained in Gelred non-toxic nucleic acid dye in the dark (dye: water = 1:10,000 ratio) for 30 min and visualized using chemiluminescence.

### Immunofluorescence

Cells were planted and fixed in the same manner as TUNEL assay. About 0.5% Triton X-100 was used for cell permeability treatment for 30 min. After discarded Triton X-100, cells were rinsed with

phosphate-buffered saline (PBS) for three times, 5 min each time. Blocked with goat serum for 1 h, then washed with PBS for three times, 5 min each time. Added primary antibody and incubated overnight at 4°C, then washed with PBS. Fluorescent secondary antibody was added and incubated in dark for 1 h. After washing with PBS, slides were mounted with DAPI to stain nuclei. The slides were observed and photographed using an inverted two-photon laser confocal microscope.

### Echocardiographic Assessment

Generally, mice were mildly anesthetized with intraperitoneal injection of 4% chloral hydrate 0.1 ml/10 g, and the hair over the chest region was removed. The mice were then placed in a supine position and transthoracic echocardiography was performed using a VINNO 6 Lab system (VINNO, Suzhou, China). Two-dimensional guided M-mode tracings were recorded in parasternal long and short axis views at the level of the papillary muscles. Left ventricular ejection fraction (EF) and fractional shortening (FS) were recorded by the system. All the measurements were obtained for greater than three beats and averaged.

### Statistical Analysis

The experimental data were analyzed using GraphPad Prism version 5 software and the data were presented as mean  $\pm$  SD. *T*-test was used to compare the data between the two groups. One-way ANOVA was used to compare the mean values of multiple groups. Tukey's *post hoc* test was used for pairwise comparison between the multiple groups. All the experiments were repeated three times and *p* < 0.05 was indicated as statistically significant.

## RESULTS

### MicroRNA-194-5p Participated in Doxorubicin-Induced Cardiomyocyte Apoptosis

We first investigated the sequences of miR-194-5p, and found that they are homologous in human, rat, and mouse according to miRBASE (miRBASE Sequence database-release 22.1). In order to explore the role of miR-194-5p in DOX-induced cardiotoxicity, rat myocardial cell line H9c2 was treated with 2  $\mu$ M DOX to simulate the cell model of DOX-induced cardiotoxicity. With 2  $\mu$ M DOX treatment, the expression of miR-194-5p increased in a time-dependent manner (Figure 1A). Transfection with miR-194-5p inhibitor could effectively suppress the expression of miR-194-5p (Figure 1B), while transfection with miR-194-5p mimic enhanced its expression (Figure 1C). Next, we further studied the potential role of miR-194-5p in DOX-induced cardiomyocytes apoptosis. When miR-194-5p expression was inhibited, DOX-induced apoptosis was significantly reduced on TUNEL assay (Figures 1D,E). In addition, inhibition of miR-194-5p attenuated DOX-induced caspase-3/7 activity elevation (Figure 1F). On the other hand, in order to demonstrate whether miR-194-5p participate in regulating the sensitivity of cardiomyocytes

to DOX, low dose of DOX (0.2  $\mu$ M) was used to treat cardiomyocytes. Under low DOX concentration stimulation, overexpression of miR-194-5p sensitized cardiomyocytes to cas-3/7 activity elevation (**Figure 1G**). Since apoptosis is the predominant cell death mode in DOX-induced cardiotoxicity, the detection of cell death rate can also reflect the degree of DOX-induced cardiotoxicity. Finally, increased cell death induced by low dose DOX was further aggravated by miR-194-5p mimic (**Figure 1H**). Taken together, miR-194-5p was upregulated in cardiomyocytes with DOX treatment, and inhibition of miR-194-5p could alleviate DOX-induced apoptosis.

## MicroRNA-194-5p Directly Targeted P21-Activated Kinase 2

It was predicted that miR-194-5p directly binds to PAK2 3' untranslated region (UTR) region on the bioinformatics program TargetScan. Moreover, PAK2 has conserved binding sites for miR-194-5p (**Figure 2A**). Hence, we tested PAK2 expression level in DOX-treated H9c2, and the result showed that its expression level was significantly decreased 12 h after treatment (**Figure 2B**). Then, we speculated the regulatory effect of miR-194-5p on DOX-induced cardiomyocyte apoptosis achieved by targeting PAK2. To verify whether miR-194-5p directly binds to PAK2, we first constructed the luciferase plasmid containing the wild type of the predicted PAK2 3'UTR binding site (WT) or mutant binding site (MT) (**Figure 2C**). Dual luciferase reporter assay demonstrated that the fluorescence activity was inhibited when the WT plasmid was cotransfected with miR-194-5p mimic. The fluorescence activity remained unchanged when the MT plasmid was cotransfected with a miR-194-5p mimic, which indicated that miR-194-5p directly bound to PAK2 3'UTR region (**Figure 2D**). Next, we transfected miR-194-5p inhibitor and mimic into H9c2 cells to investigate their effects on PAK2 protein expression. MiR-194-5p inhibitor enhanced PAK2 expression (**Figure 2E**), while miR-194-5p mimic suppressed PAK2 expression (**Figure 2F**). These results indicated that miR-194-5p directly targeted PAK2 and negatively regulated its expression.

## P21-Activated Kinase 2 Attenuated Doxorubicin-Induced Cardiomyocyte Apoptosis

We further investigated the role of PAK2 in DOX-induced cardiomyocytes apoptosis. The PAK2 plasmid was able to enhance its expression and si\_PAK2 inhibited the expression (**Figures 3A,B**). Functionally, overexpression of PAK2 significantly decreased DOX-induced apoptosis (**Figures 3C,D**) and caspase-3/7 activity (**Figure 3E**). In addition, PAK2 overexpression abolished the effects of miR-194-5p on DOX-induced cell death (**Figure 3F**), indicating that PAK2 was the downstream target of miR-194-5p. Contrarily, cell death induced by 0.2  $\mu$ M DOX was further increased with si\_PAK2 (**Figure 3G**). The above findings indicated that the PAK2 could alleviate apoptosis in H9c2 cells exposed to DOX treatment.

## X-Box Binding Protein 1 Participated in Doxorubicin-Induced Cardiotoxicity

It has been reported that DOX-induced cardiotoxicity may activate multiple UPR pathways (28). The key transcription factor XBP1s is regulated by PAK2 in the heart (24). Therefore, we first explored the XBP1s expression in DOX-induced cardiotoxicity. Similarly, H9c2 was treated with 2  $\mu$ M DOX for the indicated time, and the XBP1s expression reached peak at 3 h and decreased thereafter, which indicated the activation of the IRE/XBP1 pathway of UPR (**Figures 4A,B**).

Cas-12 as an indicator of ER-mediated apoptosis was investigated as well. The expression of its activated form—cleaved cas-12 (cl cas-12) was significantly increased 12 h onward under 2  $\mu$ M DOX treatment (**Figures 4A,C**). Next, we detected the mRNA level of XBP1s, and the result showed the same trend with its protein expression levels (**Figure 4D**). When XBP1 was activated, XBP1 mRNA was spliced and 26 bases were cut off to form the splicing XBP1, also known as its activated form (XBP1s). Thus, we measured the cDNA level after reverse transcription from total RNA. The results also showed that significant XBP1s band appeared at 3 h after DOX treatment (**Figure 4E**). It has been reported that the XBP1s can be translocated from cytoplasm to nucleus once activated (38), and this can be confirmed by immunofluorescence experiments (**Figure 4F**). Next, Thapsigargin, an ER stress inducer, was used as the positive control to verify that DOX could trigger the UPR and activate the XBP1s (**Figures 4G,H**). The inhibition of the ER stress by 4-PBA inhibited the DOX-triggered XBP1s at 3 h (**Figure 4I**). Taken together, the UPR was involved in DOX-induced cardiotoxicity, in which XBP1 was activated. In addition, the XBP1s expression reached its peak at 3 h in DOX-treated H9c2, and then decreased.

## X-Box Binding Proteins 1 Attenuated Doxorubicin-Induced Cardiomyocyte Apoptosis

Several studies have reported that XBP1s plays protective roles in the heart. In our study, we also confirmed the role of XBP1s in DOX-induced cardiotoxicity. The overexpression of XBP1s was verified by WB after transfection of XBP1s plasmid (**Figure 5A**). Cleaved caspase-12 expression increased in DOX-induced cardiomyocytes, indicating that the DOX-induced ER-related apoptosis, which decreased when XBP1s was overexpressed (**Figure 5B**). In addition, the overexpression of XBP1s significantly inhibited the DOX-induced increase in cas-3/7 activity (**Figure 5C**). Trypan blue stain assay showed the same result that the overexpression of XBP1s inhibited increased cell death rate induced by the DOX (**Figure 5D**). These results indicated that XBP1s could alleviate the ER-related apoptosis induced by the DOX and play the cardioprotective role.

Activation of XBP1 has been shown to require the presence of PAK2 in cardiomyocytes. Next, we verified the relationship between miR-194-5p, PAK2 and XBP1s on the regulation of cardiomyocyte apoptosis. Firstly, inhibition of

**FIGURE 1 |** MiR-194-5p participated in doxorubicin (DOX)-induced cardiomyocyte apoptosis. **(A)** H9c2 cells were treated with 2 μM DOX for the indicated times. The expression levels of miR-194-5p were measured by qRT-PCR. \* $p < 0.01$  vs. control. **(B)** MiR-194-5p expression after transfection with miR-194-5p inhibitor for 24 h was measured by real-time quantitative PCR (qRT-PCR). **(C)** MiR-194-5p expression after transfection with miR-194-5p mimic for 24 h was measured by qRT-PCR. **(D–F)** Suppressed miR-194-5p expression with miR-194-5p inhibitor for 24 h and exposed cells to 2 μM DOX for 24 h. Apoptosis was detected by terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) assay **(D)**. Green, TUNEL-positive nuclei; blue, 4,6-diamidino-2-phenylindole (DAPI)-stained nuclei; scale bar, 200 μm. Statistical analysis of TUNEL-positive cells **(E)** and caspase 3/7 activity **(F)** are shown. **(G,H)** Enhanced miR-194-5p expression with miR-194-5p mimic for 24 h and exposed cells to 0.2 μM DOX for 24 h. Caspase-3/7 activity **(G)** and cell death rate **(H)** are shown. All the experiments have been performed independently in triplicate, and the data were expressed as mean  $\pm$  SD. \* $p < 0.01$  as indicated.

miR-194-5p could alleviate the downregulation of XBP1s expression and the upregulation of cl cas-12 expression levels under the DOX treatment (Figure 6A). Next, PAK2 restoration by transfection with its overexpression plasmid also reduced the downregulation of XBP1s expression and the upregulation of cl cas-12 expression levels (Figure 6B). When cotransfected, XBP1s partially eliminated miR-194-5p mimic caused elevation of cleaved cas-12 and cell death (Figures 6C,D). Similarly, XBP1s also partially eliminated si\_PAK2 caused elevation of cleaved cas-12 level and cell death

(Figures 6E,F). Thus, those data suggested that miR-194-5p and PAK2 regulated DOX-induced cardiomyocyte apoptosis via XBP1s.

### MicroRNA-194-5p Was Involved in Doxorubicin-Induced Cardiotoxicity *in vivo*

We further explored the role of miR-194-5p in the DOX-induced cardiotoxicity in the mouse model. We found

that DOX treatment induced an increase in miR-194-5p expression levels in the heart (Figure 7A). Moreover, the protein expression levels of PAK2, XBP1s decreased, and cl cas-12 level increased (Figure 7B). Next, we validated the role of miR-194-5p *in vivo*. Injection with adenovirus-harbored miR-194-5p antagomir could reverse the expression of PAK2, XBP1s, and cl cas-12 induced

by the DOX (Figure 7B). Furthermore, suppression of the miR-194-5p significantly improved cardiac function (Figures 7C,D), attenuated DOX-induced cardiomyocyte apoptosis (Figures 7E,F), and ameliorated myocardial fibrosis (Figure 7G). Taken together, our *in vivo* results showed a significant protective role of miR-194-5p antagomir in the DOX-induced cardiotoxicity.

**FIGURE 4 |** X-box binding protein 1 (XBP1) participated in DOX-induced cardiotoxicity. **(A–E)** H9c2 was treated with 2  $\mu$ M DOX for the indicated times. ## DISCUSSION

Doxorubicin is the representative of anthracycline family, one of the most widely used effective antitumor drugs. However, DOX-induced cardiotoxicity is the major limiting factor for its

application, and the cardiomyopathy may not be detected until years after the DOX completion. It has been reported that 10% of patients receiving DOX developed symptomatic cardiomyopathy within 15 years after the end of treatment (39). Studies over the years have revealed that oxidative stress and mitochondrial

**FIGURE 5 |** XBP1s attenuated DOX-induced cardiomyocyte endoplasmic reticulum (ER) stress and apoptosis. **(A)** H9c2 was transfected with XBP1s-overexpressing plasmid for 24 h. The expression levels of XBP1s were determined using Western blot and the quantitative histogram was shown. **(B–D)** Enhanced XBP1s expression in H9c2 cells with XBP1s-overexpressing plasmid for 24 h and exposed to 2 μM DOX for 24 h. The expression levels of cleaved caspase-12 were determined using Western blot and the quantitative histogram was shown **(B)**. Caspase-3/7 activity **(C)** and cell death rate **(D)** were analyzed. damage are the predominant mechanisms of DOX-induced cardiotoxicity. However, the simply use of antioxidants does not provide much protection against heart damage caused by DOX (40). This suggests that the DOX-induced cardiotoxicity may be the result of multiple mechanisms. In this study, we explored the molecular mechanisms involved in ER stress-related DOX cardiotoxicity, which provides a new strategy for the prevention and control of DOX-induced cardiotoxicity.

A growing number of studies have proposed miRNAs as potential targets for the DOX-induced cardiotoxicity. For example, in the DOX-induced cardiotoxicity, miR-15b-5p, miR-23a, miR-29b, and miR-146a have been proved to be related to mitochondrial damage; miR-30 family, miR-140-5p, and miR-451 are related to oxidative stress; miR-378 is associated with the ER stress and miR-320 is related to the microvascular density (17). We reported here that miR-194-5p participated in the DOX-induced cardiotoxicity and suppression of miR-194-5p alleviated the DOX-induced cardiomyocyte apoptosis.

In recent years, the role of ER stress in the DOX-induced cardiomyopathy gained attentions. Studies have shown that the DOX caused significant ER dilatation in human hearts (27). The effectors of ER stress were activated in the DOX-treated

heart tissue, indicating that UPR was involved in regulating cardiomyocyte survival or death. Recent study has shown that PAK2 regulation of the protective ER function was through the IRE1/XBP1-dependent UPR pathway and this regulation was conferred by PAK2 inactivation of PP2A. Mice with PAK2 deletion showed defective response to ER stress, increasing cardiomyocyte damage (24). In our study, we demonstrated that PAK2 as the target gene of miR-194-5p exerted antiapoptotic effect in the DOX-induced cardiotoxicity.

In addition, the activation of the transcription factor XBP1 upregulates the expression of ER chaperone and ER associated degradation (ERAD) components to relieve ER stress and promotes cell survival (38). For example, XBP1<sup>-/-</sup> livers showed increased apoptosis, and XBP1<sup>-/-</sup> mouse embryos could not survive, while XBP1 transgenic reversed this embryonic lethality (41). In cardiovascular disease, cardiomyocyte-specific deletion of XBP1 aggravated cardiac dysfunction in ischemia-reperfusion injury, suggesting that XBP1s has a protective effect (35). The expression of XBP1s was decreased in the heart tissue of both human and rodents with heart failure, heart-specific XBP1 overexpression prevented the development of cardiac dysfunction, and XBP1s

**FIGURE 6 |** MiR-194-5p participated in DOX-induced ER stress and cardiomyocyte apoptosis through PAK2 and XBP1s. **(A)** Suppressed miR-194-5p expression with miR-194-5p inhibitor for 24 h and exposed to 2 μM DOX for 24 h. The expression levels of PAK2, XBP1s, and cleaved caspase-12 were detected by Western blot and the quantitative histogram was shown. **(B)** Enhanced PAK2 expression with PAK2-overexpressing plasmid for 24 h and exposed to 2 μM DOX for 24 h. stimulated adaptive heart growth by activating mammalian target of rapamycin (mTOR) signal (42). In vascular smooth muscle cells, XBP1s promoted the repair of vascular injury or the formation of neointima (43). These results indicated that XBP1s is involved in the regulation of cardiovascular disease and plays a protective role. Besides, other ER stress sensor, such as, binding immunoglobulin protein (BiP) was reported to bind to the IRE1 and protein kinase R-like endoplasmic reticulum kinase (PERK) *via* its nuclei

binding domain (44); ER stress with prolonged activation of the UPR-initiated apoptotic cell death *via* the upregulation of C/EBP-homologous protein (CHOP). Previous studies showed that the DOX treatment increased CHOP, BiP, and cas-12 activation to initiate apoptosis (45, 46). In the case of DOX-induced cardiotoxicity, a study also revealed that XBP1s significantly inhibited the cleaved cas-12 expression (an ER-specific apoptotic factor) and alleviated cell apoptosis (27). This present study, we measured levels of cl cas-12 by

the DOX treatment to indicate the apoptosis induced by ER stress, and further to investigate the changes of XBP1s during the ER stress. The expression of XBP1s was increased and nuclear translocated when applied DOX to H9c2 within 3 h, indicating that the DOX-induced UPR and alleviated ER stress by increasing XBP1s expression in a short time. With the extension of induction time, the level of XBP1s decreased, which was consistent with the decrease of PAK2 expression level and indicated that lack of PAK2 affected the activation of IRE/XBP1 pathway. Functionally, XBP1s as the downstream factor of miR-194-5p and PAK2, protected from DOX-induced cardiotoxicity.

Our result was consistent with other studies, showing that the XBP1s exerts cardioprotective effect. However, the expression levels of XBP1s under DOX treatment remain controversial. In a similar study of DOX-induced cardiotoxicity, the expression of XBP1s was downregulated in both 15 mg/kg (i.p.) DOX injected Institute of Cancer Research (ICR) mouse heart tissue and DOX-treated cardiomyocytes (27). In a study using SD rats, there was no significant change of XBP1s expression level in rat heart tissue after a single injection of DOX at 20 mg/kg (i.p.) (47). In another study on the role of ER stress in regulating the DOX-induced cardiotoxicity, XBP1 expression was upregulated in the heart tissues of C57BL/6J mice with a single injection of 20 mg/kg DOX (i.p.) (48). Unfortunately, neither of the latter two studies was conducted *in vitro* experiments nor was the function of XBP1 explored. These contrary results may be partially due to species heterogeneity, the difference in the dosage of DOX, and the selected myocardial tissue sites. These results indicated that ER stress is involved in the complexity of pathological mechanism regulation, and different induction conditions and external factors may cause different degrees of damage.

Currently, studies on miR-194 in cardiovascular diseases have involved in its serum expressions and the association with cardiac function impairment, suggesting the potential of miR-194 as a circulating marker. MiRNAs attracted extensive attention as potential biomarkers because they have many advantages: high conserved between species (12), partial tissue specificity (49), and stability of expression in circulation (50). In addition, miRNAs can be detected using sensitive techniques such as quantitative real-time PCR and next-generation sequencing. Therefore, whether miR-194-5p expression is also upregulated in circulation during the DOX-induced cardiotoxicity, and whether this abnormal expression can be used as a biomarker of the DOX-induced myocardial injury, remains to be further explored.

## CONCLUSION

In the DOX-induced cardiotoxicity, the miR-194-5p expression level was upregulated, and inhibition of miR-194-5p expression significantly alleviated the DOX-induced cardiotoxicity *in vitro* and *in vivo*, suggesting that the upregulation of miR-194-5p may be the cause of DOX-induced cardiotoxicity. Mechanically, miR-194-5p directly targeted PAK2 inhibited its expression, and participated in the regulation of DOX-induced cardiomyocyte apoptosis by affecting ER stress. Overexpression of PAK2 or XBP1s partially eliminated miR-194-5p induced cardiomyocytes apoptosis. Our study first identified the regulatory role of miR-194-5p/PAK2/XBP1s axis in DOX-induced cardiotoxicity, which provides a potential target for the prevention or treatment of the DOX-induced cardiotoxicity in its clinical applications.

**Background:** Viral infections are pervasive and leading causes of myocarditis. Immune-suppression after chemotherapy increases opportunistic infections, but the incidence of virus-induced myocarditis is unknown.

**Objective:** An unbiased, blinded screening for RNA viruses was performed after chemotherapy with correlation to cardiac function.

**Methods:** High-throughput sequencing of RNA isolated from blood samples was analyzed following chemotherapy for hematological malignancies ( $N = 28$ ) and compared with left ventricular ejection fraction (LVEF).

**Results:** On initial rigorous analysis, low levels of influenza orthomyxovirus and avian paramyxovirus sequences were detectable, but without significant correlation to LVEF ( $r = 0.208$ ). A secondary broad data mining analysis for virus sequences, without filtering human sequences, detected significant correlations for paramyxovirus with LVEF after chemotherapy ( $r = 0.592$ ,  $P < 0.0096$ ). Correlations were similar for LVEF pre- and post- chemotherapy for orthomyxovirus ( $R = 0.483$ ,  $P < 0.0421$ ). Retrovirus detection also correlated with LVEF post ( $r = 0.453$ ,  $p < 0.0591$ ), but not pre-chemotherapy, but is suspect due to potential host contamination. Detectable phage and anellovirus had no correlation. Combined sequence reads (all viruses) demonstrated significant correlation ( $r = 0.621$ ,  $P < 0.0078$ ). Reduced LVEF was not associated with chemotherapy ( $P = NS$ ).

**Conclusions:** This is the first report of RNA virus screening in circulating blood and association with changes in cardiac function among patients post chemotherapy,

using unbiased, blinded, high-throughput sequencing. Influenza orthomyxovirus, avian paramyxovirus and retrovirus sequences were detectable in patients with reduced LVEF. Further analysis for RNA virus infections in patients with cardiomyopathy after chemotherapy is warranted.

**Keywords:** virus, infection, RNA, immune suppression, chemotherapy, LVEF, cardiomyopathy, cancer

## INTRODUCTION

The use of chemotherapy in treatment for neoplastic disease is associated with frequent side effects and non-therapeutic toxicities (1–3). Chemotherapy associated cardiac toxicity is well-described for some chemotherapeutic agents, however, for many agents the cause of cardiac toxicity is not defined (1–3). Chemotherapy-associated heart failure has considerable associated mortality and morbidity. Amongst 3,234,256 cancer patients in the United States, 38% have died from cancer and about 1 in 3 have died from cardiovascular disease (CVD). Among the deaths from CVD, 76% were in patients younger than 35 years. The incidence of all chemotherapy-associated cardiotoxicities is reported to be ~10% in all treated patients, and this is projected to increase as more patients receive chemotherapy (1–3).

Chemotherapy induces leukocyte cytotoxicity and immune suppression with increased risk of opportunistic infections, including bacteria, fungi and viruses (4–6). Viruses are the most common cause for myocarditis in patients without cancer or chemotherapy (7–9) and myocarditis is linked to a wide array of viruses, in some cases with severe heart failure (10–17). While opportunistic bacterial and fungal infections are frequently reported after chemotherapy and immunosuppression, opportunistic viral infections are less often reported. Herpesvirus, hepatitis B/C, influenza and parainfluenza viruses, respiratory syncytial virus (RSV), and retrovirus infections have been reported after chemotherapy (7–9), but the role of viruses in myocarditis in immunosuppressed patients after chemotherapy has not been studied. Opportunistic viral infection after chemotherapy is thus predicted to contribute to heart damage and heart failure.

Among the RNA viruses, Coxsackie virus B3 (CVB3), human parvovirus B19 (B19V), measles, retroviruses and influenza viruses have been implicated in myocarditis among other viruses, and these viruses have been detected after chemotherapy (7–16). B19V and the enterovirus, coxsackievirus, are considered leading causes of viral myocarditis (7–15). DNA viruses are also linked to myocarditis, specifically cytomegalovirus (CMV), Epstein bar virus (EBV), human herpes simplex virus-6 (HHV6) also cause myocarditis (17–19). In the past year, the RNA virus, Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) infection has also been implicated in acute myocarditis (14–16). Viral infections thus present a risk for myocarditis after immune suppression with chemotherapy.

In patients with chronic unexplained heart failure positive for B19V and treated with intravenous immunoglobulins (IVIG), a significant decrease in B19V load has been observed

with improved cardiac function, symptoms, and decreased end diastolic volume (8). Other treatments that selectively target specific viruses, such as acyclovir that inactivates herpes simplex virus (HSV) DNA polymerase for herpes myocarditis or antiretroviral therapy for human immunodeficiency virus (HIV) infections have proven beneficial (8–19). Development of new vaccines to target viral infections are highly effective as for SARS-CoV-2 and COVID-19, but viruses with the potential to cause chemotherapy induced myocarditis must be identified in order to develop effective vaccines and treatments.

Accordingly, we postulated that immune suppression caused by chemotherapy, or by the cancer itself, will increase susceptibility to viral infections, and therefore myocarditis. This study presents an unbiased, blinded screen for RNA viruses in blood samples obtained from patients after chemotherapy for hematological malignancies. In this pilot study, reductions in measured left ventricular ejection fraction (LVEF) on 2D echocardiogram were correlated with measured levels of detected RNA virus gene signatures. To the best of our knowledge, this is the first screen for detectable RNA virus sequences in blood samples from cancer patients with evidence for myocarditis and reduced LVEF after chemotherapy. Information on opportunistic viral infections seen after immune suppression and chemotherapy will foster a defined preventative approach, such as development of vaccines or treatment with specific anti-viral agents designed to reduce the risk of cardiac damage.

## MATERIALS AND METHODS

### Patient Population

Twenty-eight patients were enrolled in the Cardio-Oncology (AL) and the Hematologic Malignancies / Stem Cell Transplantation clinics (SC, JM) at the University of Florida after written informed consent. All patients and samples were assigned a randomized number after informed consent. The study was approved by the Institutional Review Boards (IRB) at all institutions involved in the study.

Patient ages ranged from 18 to 85 years; all had a diagnosis of cancer and a range of chemotherapeutic agents including dexamethasone, lanolodimide, rituximab, bortezomib, and cyclophosphamide, as well as combinations as noted (**Table 1; Figure 1**). The majority of patients had a history of hematological malignancy (25/26 hematological malignancy and 1/26 breast cancer) (**Table 1**). Six patients had a history of prior diagnosed ischemic heart disease, one with documented coronary artery disease and stent implant. Of the enrolled patients, 26 had complete viral sequencing (ST, SS-C) (**Table 1**). Eighteen patients had LVEF measured post chemotherapy, 22 patients had

dexa, dexamethasone; RVD, revlimid, velcade, dexa; ASCT, autologous stem cell transplant; CTX, cyclophosphamide; DCIS, ductal carcinoma in situ; VCR, vincristine; CVD, velcade, cyclophosphamide, dexa; Mel, melphalan; Dara, daratumumab; VD, velcade and dexamethasone; RT, radiation therapy; VBCP, vincristine, BCNU, cyclophosphamide, and prednisone; Thal/Dex, thalidomide and dexamethasone; PD, pomalidomide and dexamethasone; PD+ Elo, PD and Elotuzumab; VTD, velcade, thalidomide and dexa; VAD, vincristine, Adriamycin and dexamethasone; RCD, revlimid, cyclophosphamide and dexa; VTD-PACE, Velcade, thalidomide, dexamethasone, platinum, Adriamycin, cyclophosphamide, and etoposide; TAM, tamoxifen.

LVEF measured before chemotherapy, and 16 had both. One patient had confirmation of LVEF by cardiac catheterization. Chemotherapy given was recorded for each patient. Echocardiograms were ordered by the attending physician based upon perceived clinical risk, but were not mandated. Cardiac dysfunction was defined as a decrease in ejection fraction (EF)  $<45\%$  as demonstrated on echocardiography. LVEF data was available but more comprehensive data such as fractional shortening was not provided.

## Virome Sequencing of Blood Samples

Blood samples were obtained 2–4 weeks after chemotherapy, once informed consent was obtained. Venous blood was collected in clinic at 2–4 weeks after the last chemotherapy in tubes containing 3 mL of Ethylenediaminetetraacetic acid (EDTA). RNALater (Life Technologies, Bleiswijk, The Netherlands) was added at a ratio of 2:1 RNALater to whole blood and samples stored at  $-80^{\circ}\text{C}$  until analysis. Blood samples were anonymized blood samples and were sent to St Jude's Hospital (SCC, ST); where investigators were masked to cancer type, chemotherapy, and LVEF findings.

Samples were fragmented prior to RNA extraction as previously described (20). RNA was isolated using the QIAamp cadior Pathogen Mini kit (Qiagen, Hilden, Germany) according to manufacturer's instructions. First strand synthesis was completed using the random-primer technique described by Wang et al. (21). Briefly, Super Script III (Invitrogen, Carlsbad, CA, USA) first strand synthesis was carried out using primer A (5'-GTTTCCCAGTCACGATANNNNNNNNN), followed by Sequenase (Affymetrix, Santa Clara, CA, USA) for second

strand synthesis. Finally, PCR amplification utilized Primer B (5'-GTTTCCCAGTCACGATA) for 40 cycles. Samples were electrophoresed in an agarose gel to confirm product.

Samples were run on a 1% agarose gel and imaged to confirm the presence of DNA (between 500 bp and 1 kb). To prepare for sequencing, samples were purified using AMPure XP beads (Beckman Coulter, Brea, CA, USA) followed by analysis on a Qubit fluorometer (Thermo Fisher Scientific, Waltham, MA, USA). A Nextera DNA library preparation kit (Illumina, San Diego, CA, USA) was used for sample genome sequencing using the Illumina MiSeq Amplicon application for virome reference genomes. Quality control of input nucleic acid and final libraries were checked using Agilent TapeStation 4200.

## Bioinformatics Analysis

In an initial analysis, Illumina sequencing data sets were examined for viral pathogen detection. The quality of raw reads was assessed using FastQC (version 0.11.9) (<https://www.bioinformatics.babraham.ac.uk/projects/fastqc/>). Trimmomatic was used to trim the adapters from the paired-end reads (22). Taxonomic classification was performed for blood samples using Kraken2 (version 2.0.7b). Illumina sequencing data sets were initially analyzed for detection of RNA viruses (23–25). The RNA viral reads that were viral-like were also checked using BLASTn against a viral RefSeq database. Sequencing data is available, Bioproject accession number NCBI, PRJNA794842, temporary submission ID SUB10902989, release date: 2022-01-06.

For the broader viral RNA sequence analysis (SS-C, ST), a custom viral database, containing complete viral genomes cross referenced to RefSeq (<ftp://ftp.ncbi.nlm.nih.gov/refseq/release/>)

with taxonomic classifications, was built using Kraken2 (26). Following that, Kraken reports were analyzed, visualized and summarized using Pavian [(27), **Supplementary Figure 1**]. The database used for taxonomic classification included all viral genomes in RefSeq. Contigs sequences were used to identify the viral genetic sequences. To verify that human endogenous retrovirus K (HERV K) is detected correctly, we extracted the raw reads that classify as HERV K. The extracted raw retrovirus K reads were then mapped to human endogenous retrovirus reference genome (NC\_022518.1) and human reference genome (GRCh38) separately. The quality of mapping to both reference genomes was assessed.

## Statistical Analysis—Correlation of Viral Genetic Sequences With Cardiac Function and Chemotherapy

Levels of viral gene sequences detected in blood samples were correlated with heart function (LVEF) before and after chemotherapy using simple regression analysis with confirmation by our statisticians (PM,AV,SK at ASU; ST, SS-C at St Junes). All statistics were performed using Statview, version 5.01 (SAS, Inc., Cary, NC) or Graphpad Prism (GraphPad). Multiple-group comparisons were performed using analysis of variance (ANOVA) with Fishers protected least significant difference (PLSD) and unpaired two-tailed Student's *t*-test for subgroup analysis. A  $P < 0.05$  is considered significant.

## RESULTS

### Analysis of Associations Between Cardiac Function and Chemotherapy

No significant correlation was detected for the specific chemotherapy given to each patient and LVEF post chemotherapy, measured as LVEF (**Table 1**);  $p = 0.5339$  for dexamethasone (**Figure 1A**),  $p = 0.3158$ ; lenolidamide (**Figure 1B**),  $p = 0.3158$ ; rituximab (**Figure 1C**),  $p = 0.8859$ ; bortezomib (**Figure 1D**),  $p = 0.4179$ ; and cyclophosphamide (**Figure 1E**),  $p = 0.3609$ . When a chemotherapeutic agent was used in only one of the patients, this was considered an inadequate number to allow analysis for correlation with LVEF. Analysis of changes in LVEF with specific cancer diagnosis demonstrated no significant correlation between diagnosed cancer type and LVEF (**Figure 1F**,  $p = 0.8659$ ). No significant association was made between patient sex and measured LVEF ( $p = 0.8107$ , **Figure 1G**). Simple regression analysis did demonstrate a significant correlation between an increased age of patients and reduced LVEF, both pre and post chemotherapy (for post chemotherapy— $r = 0.510$ ,  $p < 0.0365$ ) (**Figure 1H**). The minority of patients were receiving cardiovascular medications at enrollment, 6/ 26 patients had diagnosis of IHD listed (**Table 1**; ANOVA  $P = 0.056$ ) and diagnosed IHD and CVD medications were not associated with changes in LVEF ( $p = 0.8659$ ).

## High Throughput Sequencing of RNA Virus in Blood Samples From Patients

Low levels of RNA virus sequences were detected in blood samples isolated from patients post chemotherapy. Detection of virus sequences using a strict, blinded analysis with either Blastn or Kraken 2 programs, and removing all potential contaminating human sequences, detected low levels of paramyxovirus and orthomyxovirus, as representative of potential opportunistic infections. The avian Avulavirus, a paramyxovirus, and Influenza A, an orthomyxovirus, were consistently identified on sequence analysis using both methods for RNA Seq analysis (Blastn and Kraken 2), indicating low levels of these RNA viruses after chemotherapy. The paramyxovirus avian Avulavirus and the orthomyxovirus Influenza A were the most frequently identified sequences.

## Effects of Chemotherapy on Strict RNA Virus Sequence Read Detection

Potential correlations were assessed for detected RNA virus sequences and treatments with individual chemotherapeutic agents. Levels of virus sequences detected were increased with bortezomib and dexamethasone (**Figure 2**), however, there was only a trend toward increased detection of virus sequences in blood samples;  $p = 0.0623$  for orthomyxovirus detection (**Figure 2A**),  $p = 0.1726$  for paramyxovirus detection (**Figure 2B**) and  $p = 0.0767$  for retrovirus sequences (**Figure 2C**) after bortezomib and  $p = 0.1061$  for paramyxovirus (**Figure 2D**) after dexamethasone, none reaching significance. Analysis of a combined count of all detected RNA virus sequences in patients with bortezomib chemotherapy again detected a borderline increase ( $p = 0.053$ ) (**Figure 2E**). Lenolidamide and cyclophosphamide treatment had no clear trend nor significant change in RNA virus gene sequence detection. In contrast, rituximab treatment was associated with a non-significant trend toward decreased virus sequence detection (not shown). Detection of RNA virus sequences in blood samples from cancer patients was not linked to gender ( $p = 0.1028$ , **Figure 2F**) nor age ( $p = 0.245$ , **Figure 2G**).

## Initial Strict Analysis of RNA Virus Sequence Detection and Cardiac Function After Chemotherapy

On an initial rigorous, or strict, analysis, removing all potential contaminating human, bacterial or phage sequences, RNA virus sequences in the paramyxovirus (28) and orthomyxovirus (29) families were detected. Virus sequence detection was read blinded by four investigators (ST, SS-C, AV, AL). No significant correlations were detected for measured LVEF post chemotherapy;  $r = 0.177$  for paramyxovirus ( $p = 0.4961$ , **Figure 3A**), and  $r = 0.208$  for orthomyxovirus ( $p = 0.4229$ , **Figure 3B**). Screening for LVEF and a combined analysis of paramyxovirus and orthomyxovirus virus sequences detected a minimal, but again non-significant, increase in the correlation with reductions in LVEF reported on 2D echo post chemotherapy ( $r = 0.233$ ,  $p = 0.3732$ , **Figure 3C**). This would suggest that RNA virus gene signatures are detectable at low levels in blood samples

from patients with reduced LVEF post chemotherapy, but do not have a significant correlation for reduced LVEF for individual detectable viruses in this small patient cohort.

## Secondary Custom Database Analysis of RNA Virus Sequence Detection and Cardiac Function After Chemotherapy

A secondary, broad, customized Kraken2 database was next designed to detect a wider spectrum of RNA virus sequences as a metagenome analysis platform. This secondary analysis was performed without rigorous filtering of potential human genome sequences, and accepting both unidirectional as well as bidirectional reads. With this broad analysis an increased correlation was detectable for RNA virus sequences (Illustrated via Pavian software, **Supplementary Figure 1**). Bidirectional reads were used for analysis of correlations between detected virus gene signatures with measured LVEF post chemotherapy. Correlations of virus sequence detection with LVEF recorded prior to chemotherapy was used as a control to assess changes in LVEF prior to treatment with chemotherapy.

Paramyxovirus sequence detection and retrovirus sequence detection, using bidirectional reads from this more permissive analysis, had increased correlation when comparing LVEF post chemotherapy and LVEF measured pre chemotherapy; For paramyxovirus the correlation increased from  $r = 0.484$  pre chemotherapy LVEF ( $P < 0.0452$ ) to  $r = 0.592$  for LVEF measured post chemotherapy ( $P < 0.0096$ ,

**Figure 4A**), with a clear increase in significance. Albeit both achieve significance.

Conversely, orthomyxovirus sequence detection, specifically for influenza A, had similar correlations when comparing paramyxovirus sequence reads to LVEF measured prior to or after chemotherapy ( $r = 0.513$  pre,  $P < 0.0248$  and  $r = 0.483$  post,  $P < 0.0421$ ). Although both analyses for influenza A reached significance prior to or after chemotherapy, the fact that there was a significant and greater correlation prior to chemotherapy would suggest no specific association between orthomyxovirus detection and developing cardiac dysfunction after chemotherapy. Overall, orthomyxovirus and paramyxovirus sequences were again detected in this broad, less strict analysis, but with increased numbers of detectable reads using this custom platform.

Other RNA virus sequence reads were also detected using this broad analysis (**Figure 5**). One of the most prominent was the retrovirus HERV K (30). For retrovirus sequences, the correlation increased from  $r = 0.034$  for LVEF measured pre chemotherapy ( $P = 0.8904$ , non-significant) to  $r = 0.453$  post chemotherapy with a borderline trend toward significance ( $P = 0.0591$ , **Figure 5C**). Retrovirus sequences detected were predominantly human endogenous retrovirus K (HERV K), a retrovirus commonly detected in the human genome. Retrovirus sequences may represent activation from the native human cell genome, during the stress of cancer, chemotherapy or extrinsic infections.

Among other sequences detected there were Molivirus, Pandoravirus and Pandoravirus dulcis, Lambdina fiscellaria

nucleopolyhedrovirus, Leukania separata nucleopolyhedrovirus, and several phage including Proteus virus mirabilis Isfaham, Aeromonas virus 25AhydR2PP and Aes 12, Caulobacter virus CcrBL10, Vibrio phage Eugene 12A 10, Streptomyces virus Izzy, and Pseudomonas phage OBP and PAJU2. None of these additional virus sequence reads demonstrated significant correlations for changes in LVEF post or even pre chemotherapy for hematological cancers (Figure 5 illustrates some of these analyses). For these virus sequences compared to LVEF post chemotherapy, the following  $r$  values were obtained: Molivirus  $r = 0.251, P = 0.3306$ ; Pandoravirus and Pandoravirus dulcis  $r = 0.015, P = 0.9538$ ; Lambdina fiscellaria nucleopolyhedrovirus

$r = 0.435, P = 0.3289$ ; Leukania separata nucleopolyhedrovirus  $r = 0.114-0.201, P = 0.4372-0.6725$ ; and several phage including Lactococcus phage BK5-T  $r = 0.228, P = 0.3625$ ; Streptomyces virus Izzy  $r = 0.221, P = 0.4104$ ; Proteus mirabilis virus Isfaham  $r = 0.433, P = 0.0826$ ; Aeromonas virus 25AhydR2PP  $r = 0.447, P = 0.1088$ ; Aes 12  $r = 0.124, P = -0.6483$ ; Caulobacter virus CcrBL10  $r = 0.225, P = 0.3849$ ; Vibrio phage Eugene 12A 10  $r = 0.376, P = 0.5429$ ; Pseudomonas phage OBP and PAJU2,  $r = 0.240-0.356, P = 0.1927-0.3536$ . A circular DNA Anellovirus, signature was detected in one patient with multiple myeloma and demonstrated no correlation.

A potential correlation between changes in LVEF pre and post chemotherapy with an analysis of a combined RNA virus sequence reads for virus sequence detection where trends toward increased RNA viral sequence correlations with reduced LVEF were demonstrated was then examined. A combined read for detected paramyxo- orthomyxo- and retro-virus sequences was assessed using this broad screen (Figure 4D). On this final analysis of combined RNA virus sequences for each sample, the correlation increased from  $r = 0.233$  ( $p = 0.3732$ ) for pre chemo LVEF to  $r = 0.621$  ( $P < 0.0078$ ) for post chemo LVEF, a markedly significant increase. Thus, increased detection of three detectable RNA virus sequence reads, paramyxo, orthomyxo- and retro-viruses after chemotherapy did demonstrate an apparent significant association with measured reductions in LVEF after chemotherapy (Figure 4D).

## DISCUSSION

Dilated cardiomyopathy in cancer patients is a critically important complication after chemotherapy produced by cardiotoxicity with associated increased mortality (1–3). Immunosuppression with secondary opportunistic viral infection increases the risk for virus-induced myocarditis and heart damage after chemotherapy (4–9). Individual chemotherapeutic regimens have proven cardiotoxicity, but there are multiple molecular mechanisms for cardiac damage that differ for individual chemotherapeutic agents and some have no known etiology for cardiotoxicity (31–35). Viral infections are a leading cause for myocarditis in patients without

cancer or chemotherapy (7–16, 36) and immunosuppression after chemotherapy increases the risk for opportunistic viral infections. We have performed a pilot study to screen for potential correlations between RNA virus sequences detected in blood samples and reduced LVEF post chemotherapy in patients with hematological tumors.

Chemotherapy is used for both hematological cancers and solid tumors with proven cytotoxicity, with a variety of non-therapeutic and potentially adverse side effects. Myocardial toxicity leads to left ventricular dysfunction (LVD), heart failure (HF), endothelial dysfunction, thrombogenesis, ischemia, vasospasm, pericardial disease, hypertension, and rhythm disturbances (1–3, 31–35). Incidence and cardiotoxic effects vary with individual chemotherapy agents. The incidence of LVD is 3–26% for Doxorubicin (anthracycline), 7–28% for Cyclophosphamide, 17% for Ifosfamide, 1–3% for Bevacizumab 2–28% for Trastuzumab therapy and 0.5–1.7% for Imatinib mesylate therapy (1, 2). Causes for cardiac toxicity varies from direct cardiomyocyte toxicity to vascular injury. Several mechanisms have been proposed for each class of agent, but individual chemotherapeutic reagents have differing molecular targets and reported causes for heart damage; there is, as might be expected, no unifying mechanism. The mechanism underlying anthracycline-induced cardiotoxicity has been reported as interference with topoisomerase II beta and secondary free-radical formation; apoptosis; transcriptional changes in intracellular adenosine triphosphate (ATP); reduced sarcoplasmic reticulum calcium-ATPase expression; prolonged depression in cardiac glutathione peroxidase

activity; and respiratory defects associated with mitochondrial deoxyribonucleic acid damage (12, 31–35). Cyclophosphamide-induced cardiotoxicity is postulated to be caused by endothelial injury through toxic metabolites that damage cardiomyocytes and secondary intracapillary microemboli and coronary vasospasm (1, 2). The mechanism of HF associated with bevacizumab is believed to be associated with uncontrolled HTN and inhibition of vascular endothelial growth factor (VEGF)/VEGF receptor signaling (1–3). Damage to the myocardium after treatment with chemotherapy thus has differing etiologies dependent upon the underlying cancer, treatment used, and the cause is incompletely defined for many newer chemotherapies. The potential for viral infection and secondary myocarditis after immunosuppression with chemotherapy for cancer has not been systematically examined as a potential cause for cardiomyopathy after chemotherapy.

In this study we measured RNA virus sequences in blood samples obtained from patients after chemotherapy using RNA Seq screening, RNA isolates were assessed both by an initial rigorous analysis that removed any potential human sequence contamination as well as with a subsequent broader, customized virome analysis. This was an unbiased screen for the detection of RNA virus sequences in venous blood samples in cancer patients receiving chemotherapy. On the initial more rigorous analysis, both paramyxovirus and orthomyxovirus sequences were detectable, but had no clear correlation with changes in LVEF (**Figure 3**). The orthomyxovirus Influenza A has a well-known association with viral myocarditis, but demonstrated similar correlations with LVEF measured prior to, or after, chemotherapy (6–9). Both paramyxovirus and orthomyxovirus families have been reported as causes for myocarditis in patients without known prior cancer or chemotherapy. The detectable sequences for orthomyxovirus matched to influenza A (29) and those for paramyxovirus with avulavirus (28). On a secondary broad analysis using a customized screen, we were able to detect larger numbers of RNA virus sequences for orthomyxovirus influenza A and paramyxovirus Avulavirus, as well as a larger array of RNA viruses including retroviruses, insect viruses and phage. In this second analysis we identified correlations between the detected paramyxovirus and retrovirus with changes in LVEF.

The increase in the paramyxovirus Avulavirus, sequences does demonstrate an increase in sequence detection and reduced LVEF after chemotherapy, with a greater correlation for post chemotherapy LVEF than for pre-chemotherapy LVEF. Orthomyxovirus influenza A was also detected, but with similar detected sequence counts and correlations for LVEF measured pre- or post-chemotherapy (**Figure 4B**); this correlation was stronger for pre-chemotherapy. Influenza is a common upper respiratory infection and the detection of this orthomyxovirus may be attributed to the prevalence of influenza A virus in the general population, with a generalized increase in an immunocompromised cohort. This suggests a general association of influenza A, the orthomyxovirus, with a reduction in LVEF that is unrelated to chemotherapy. The paramyxovirus Avulavirus sequence detection was also detectable, but the correlation was greater for LVEF measured after chemotherapy, albeit a small increase (**Figure 4A**). On the secondary, broader analysis, the greatest increase in correlation was seen with the

HERV K retrovirus sequence on the post chemotherapy sample. Simple regression analysis for pre-chemotherapy LVEF analysis exhibited a flat, unresponsive regression with no evidence for correlation with LVEF pre chemotherapy, but with a clear inverted, negative correlation for detected HERV K sequences with post-chemotherapy LVEF (**Figure 4C**).

Retroviruses are reported to represent up to 8% of the human genome (37–41). Retrovirus sequence detection may represent activation of latent human retroviruses rather than opportunistic infection, as has been reported. Retrovirus K reads may represent reactivation from the human genome induced by the stress from chemotherapy and/ or cancer. Blast confirmation indicated that all reads belonged to the human genome suggesting reactivation rather than *de novo* infections. HERV-K is the most transcriptionally active retrovirus in man, representing up to 8% of the human genome, and thus may also represent a contamination. HERV-K has been associated with neurodegenerative disorders, cancer, and an overall higher tumor burden (38–41). HERV K genes, like nuclear protein-1, has important roles in the generation of reactive oxygen species and other tumorigenic characteristics that may act in synergy with chemotherapeutics to decrease LVEF. HERV-K has also been reported to be upregulated after chemotherapy and could suggest that the stress of chemotherapy or the immunosuppression may have induced increased HERV-K expression.

Phage infect bacteria and alter bacterial responses after chemotherapy. We detected some phage sequences and these might be considered contaminants, as are the pandoraviruses. However, recent reports have demonstrated high levels of phage in many organs outside the gut (42, 43). Increased levels of phage are reported in the circulating blood in patients with increased gut permeability in leukemic patients where “leaky gut” is suspected to allow phages to translocate from the gut to the plasma (43). In this study, no correlation was uncovered between the detected phage sequences and insect virus reads with LVEF post chemotherapy (**Figure 5**). No correlation was found between anellovirus and reduced LVEF. These identified virus reads likely represent incidental detection of DNA viruses during analysis of RNA virus cDNA.

Bortezomib was associated with a borderline increase in detection of viral sequences ( $P = 0.0532$ ). Other than age, none of the other parameters, chemotherapeutic agent, gender, cancer diagnosis and none of the other chemotherapeutic drugs demonstrated clear correlations with reduced LVEF pre- or post-chemotherapy.

This study was realized as an unbiased survey, a pilot study, to detect RNA virus sequences in blood samples in post chemotherapy patients with hematological cancers. In this study we were able to detect paramyxovirus, orthomyxovirus, and retroviruses in venous blood samples taken post chemotherapy for hematological malignancy. With a broad analysis, correlations were detected with LVEF measured post chemotherapy. This is, however, limited to a correlation without a definitive cause-and effect. A comprehensive analysis of correlations between detected virus sequences and reduced LVEF with scheduled blood samples, LVEF analysis, and heart damage markers prior to and after chemotherapy should be considered and has the potential to demonstrate chemotherapy induced

immune suppression and the risk of heart damage due to viral infection and/or reactivation.

## LIMITATIONS OF STUDY

This study is limited by the small numbers of patients studied, variability in temporality of blood sample collection, as well as an incomplete data set for echocardiogram measured LVEF and longer term follow up for cardiac function. A control group of patients not receiving chemotherapy is not available, however the pre-treatment LVEF analysis by 2D echo provide an internal control. Echocardiograms were ordered at the discretion of the attending clinic physician and not all patients had LVEF measured.

## CONCLUSIONS

In summary, low levels of RNA virus sequences are detectable in venous blood samples taken from patients with hematological cancers after chemotherapy. Analysis of these detected RNA virus sequences suggest that there is increased detection of RNA virus sequences in blood samples from patients after chemotherapy. Chemotherapeutic immune suppression increases the risk for chemotherapy induced myocarditis and cardiomyopathy with reduced LVEF. A comprehensive, structured study of cancer patients for sequential detection for RNA virus sequences after chemotherapy and correlation with LVEF analysis at predetermined follow up times, as well as an analysis for other markers for cardiac damage and immunosuppression is needed. A structured sequential analysis, as well as a comparison to patients without chemotherapy, will allow identification of opportunistic viral infections and identify potential approaches to prevent or treat viruses identified as risk factors for myocarditis and cardiomyopathy after chemotherapy.

## CLINICAL PERSPECTIVES—TRANSLATIONAL OUTLOOK

Further investigation into the role of RNA viruses as a significant underlying etiology for myocarditis and cardiomyopathy after chemotherapy with associated immunosuppression is needed.

Cancer mortality has improved due to earlier detection *via* screening, as well as due to novel cancer therapies such as tyrosine kinase inhibitors and immune checkpoint inhibitions. However, similarly to older cancer therapies such as anthracyclines, these therapies have also been documented to cause cardiotoxic events including cardiomyopathy, myocardial infarction, myocarditis, arrhythmia, hypertension, and thrombosis. Imaging modalities such as echocardiography and magnetic resonance imaging (MRI) are critical in monitoring and evaluating for cardiotoxicity from these treatments, as well as in providing information for the assessment of function and wall motion abnormalities. MRI also allows for additional tissue characterization using T1, T2, extracellular volume (ECV), and delayed gadolinium enhancement (DGE) assessment. Furthermore, emerging technologies may be able to assist with these efforts. Nuclear imaging using targeted radiotracers, some of which are already clinically used, may have more specificity and help provide information on the mechanisms of cardiotoxicity, including in anthracycline mediated cardiomyopathy and checkpoint inhibitor myocarditis. Hyperpolarized MRI may be used to evaluate the effects of oncologic therapy on cardiac metabolism. Lastly, artificial intelligence and big data of imaging modalities may help predict and detect early signs of cardiotoxicity and response to cardioprotective medications as well as provide insights on the added value of molecular imaging and correlations with cardiovascular outcomes. In this review, the current imaging modalities used to assess for cardiotoxicity from cancer

treatments are discussed, in addition to ongoing research on targeted molecular radiotracers, hyperpolarized MRI, as well as the role of artificial intelligence (AI) and big data in imaging that would help improve the detection and prognostication of cancer-treatment cardiotoxicity.

**Keywords:** cardiotoxicity, cardiovascular imaging, big data, cancer therapy-associated cardiotoxicity, molecular imaging

## INTRODUCTION

Cancer incidence is expected to increase by 50% by 2050, but over the past two decades, cancer mortality has improved in part due to earlier detection *via* screening and the advent of novel therapies such as tyrosine kinase inhibitors (TKI) for cancers like chronic myelogenous leukemia (CML), liver, gastrointestinal and lung cancers, as well as immunotherapy, such as checkpoint inhibitors, for metastatic disease and an expanding list of indications including triple negative breast cancer, lung cancer, melanoma, bladder cancer, and renal cell cancer (1–6).

However, with the rise of newer oncologic therapies, there have been a spectrum of adverse cardiovascular toxicities including cardiomyopathy (CM), myocardial infarction, myocarditis, arrhythmia, hypertension (HTN) and thrombosis that have been associated with these agents. More traditional cardiotoxic agents like anthracyclines (i.e., doxorubicin), one of the most widely used class of chemotherapeutics due to improved overall cancer and survival outcomes has been shown to alter myocardial energetics, promote mitochondrial dysfunction, increase reactive oxygen species levels leading to activation of matrix metalloproteases, inhibit topoisomerase IIb and cause DNA strand breaks, thereby promoting cardiomyopathy (7–9).

HER2 inhibitors like trastuzumab has also been shown to increase risk of CM *via* antagonizing important pro survival as well as other important signal transduction pathways for metabolism in the heart (10). Platinum agents like cisplatin have been shown to increase oxidative stress and increased apoptosis and has been associated with cardiomyopathy in rare instances (11). Alkylating agents like cyclophosphamide, which can cause oxidative damage and direct endothelial cell damage have been linked to myocarditis and cardiomyopathy (12). Antimetabolites like 5 fluorouracil (5FU), which is commonly used in head and neck cancers as well as gastrointestinal cancers has been shown to increase risk of coronary vasospasm and myocardial infarction (13, 14). Multiple myeloma therapies (bortezomib, lenalidomide) and vascular endothelial growth factor (VEGF) inhibitors like bevacizumab have been associated with thrombosis and hypertension by promoting endothelial cell dysfunction (15–18). TKIs like ibrutinib has been associated with atrial fibrillation,

while other TKIs such as ponatinib, sorafenib, sunitinib have been associated with CM and myocardial infarction (MI) (19–21).

Of the close to 2 million patients diagnosed with cancer in 2019, it is estimated that 38.5% are eligible for ICI therapy (22, 23). In addition to increased risk of myocarditis, pericarditis and vasculitis, immune checkpoint inhibitors (ICI) have been associated with increased risk of plaque rupture/acceleration of atherosclerosis and thrombosis (24). ICI myocarditis is characterized by lymphocytic infiltration with CD4 and CD8 cells and mortality is high if not identified and if left untreated (25).

Newer immunotherapies may also increase risk of myocarditis, such as cellular therapies like CART and molecular inhibitors such as CCR4 antagonist, mogamulizumab, which is used to treat T cell lymphomas (26–28). However, evaluation of the earliest signs of immune cell infiltration in the myocarditis process is limited (Table 1; Figure 1). Imaging modalities like echocardiography (echo) and magnetic resonance imaging (MRI) are routinely used to monitor and evaluate for the aforementioned oncologic therapy related cardiotoxicity, with both allowing for assessment of function and wall motion abnormalities and MRI allowing for additional tissue characterization using T1, T2, extracellular volume (ECV) and delayed gadolinium enhancement (DGE) assessment. While nuclear studies like multi-gated acquisition (MUGA) scans have fallen out of favor for the evaluation of cardiomyopathy mediated by oncologic therapy due to the higher sensitivity, and availability of echo and MRI, emerging nuclear imaging using molecularly targeted radiotracers may confer more specificity and help elucidate the mechanisms of cardiotoxicity, many of which are already in clinical use for oncology purposes and thus can be adapted to evaluate their signal/role in cardiotoxicity (Table 1). In addition to molecular targets, hyperpolarized MRI has emerged as a potential imaging modality to evaluate effects of oncologic therapy on cardiac metabolism and has reached human studies. Finally, artificial intelligence and big data of imaging modalities including electrocardiograms may be able to help predict and detect early signs of cardiotoxicity and response to cardioprotective medications once cardiomyopathy develops but also help provide insights on diagnostic and prognostic value of molecular based imaging. We review current imaging modalities used to assess for cardiovascular toxicities associated with oncologic therapies and highlight ongoing research in the areas of molecular imaging, targeted molecular radiotracers and hyperpolarized MRI as well as the role of artificial intelligence (AI) and big data in imaging that would help improve detection, prognostication of oncologic therapy related cardiotoxicity.

**Abbreviations:** AI, artificial intelligence; CM, cardiomyopathy; CML, chronic myelogenous leukemia; DGE, delayed gadolinium enhancement; DNA, Deoxyribonucleic acid; ECV, extracellular volume; GLS, global longitudinal strain; ICI, checkpoint inhibitors; HER2, human epidermal growth factor receptor 2; HF, heart failure; HTN, hypertension; MI, myocardial infarction; MUGA, multigated acquisition; ROS, reactive oxygen species; TdP, torsades de pointe; TKI, tyrosine kinase inhibitor; VTE, venous thromboembolism.

Neratinib				
Tucatinib				
<b>Anti metabolite</b>				
5 FU	Coronary vasospasm (14, 71)	CT coronary, PET or SPECT to rule out obstructive disease	Hyperpolarized magnetic resonance	Clinical

## CURRENT IMAGING MODALITIES USED TO INTERROGATE ONCOLOGIC THERAPY CARDIOTOXICITY

### Echo and MRI in Evaluation of Cardiotoxicity

Cardiotoxicity due to anthracycline use (often dose dependent, but can occur at any dose) are common, up to 5% with cumulative doses <400 mg/kg, but up to 20% for those treated with 700 mg/kg or more (72). HER2 inhibitor mediated cardiomyopathy can occur in 5–10% of patients and is increased when given in conjunction with anthracyclines up to 27% (73, 74). Oncologic therapy mediated cardiomyopathy can be evaluated by traditional imaging modalities such as echo and MRI, which are able to evaluate wall motion, left and right ventricular function and even early signs of toxicity *via* changes in strain, namely global longitudinal strain (75, 76). The European Society for Medical Oncology (ESMO) and the American Society of Echo (ASE) recommend 2D/3D echo or MRI for assessing left ventricular function including strain for monitoring of known cardiotoxic therapies such as anthracyclines or anti-Her2 therapies and the American Society of Clinical Oncology (ASCO) recommends echo or MRI as first line imaging modalities with MUGA as a second line if echo/MRI are not available or if not technically feasible for MRI (77–81). Due to reduced variability compared to 2D echo, 3D echo or MRI are recommended for sequential follow up (82).

In addition to being the gold standard for volumetrics and ejection fraction, MRI has additional evaluation capabilities including tissue characterization for injured cells such as changes in ECV and increased native T1 times, shown with anthracycline

use and increased T2 relaxation times with anthracycline toxicity (83–86). The presence of DGE post trastuzumab, a HER2 inhibitor, was associated with cardiomyopathy (87).

### Strain as a Predictor of Cardiomyopathy

Feature tracking global longitudinal strain (GLS) was first used in echo to show that it could be predictive of future cardiomyopathy in multiple studies of cancer patients undergoing cardiotoxic chemotherapy with anthracycline or trastuzumab. For example, an increase in GLS >12 or 15% was associated with a significant drop in LVEF >10% 6 months after in several studies (88, 89). MRI has subsequently shown that use of tagging, feature tracking strain or fast strain encoded (SENC) assessment are sensitive and highly accurate in detecting subclinical cardiotoxicity as evidenced by an increase in GLS for patients on cardiotoxic chemotherapy such as anthracyclines, with SENC having a higher accuracy that was less dependent on loading conditions (90–94). However, strain assessment in MRI is largely used in a research setting and is not routinely used in the clinical practice yet.

### MRI Evaluation of Adverse Immune Related Cardiac Events

ICI myocarditis can occur in 1–2% of patients and has a high mortality of up to 50% if untreated (25, 95). MRI has become a work horse for evaluation of immunotherapy related cardiotoxicities. In addition to T1, and ECV changes, T2 abnormalities allow for assessment of myocardial edema in patients on checkpoint inhibitors with concern for myocarditis or pericarditis and DGE, a marker of myocardial injury

**FIGURE 1 |** Imaging modalities and evaluation of cardiotoxicities of oncologic therapies. For evaluation of peripheral artery disease (PAD) (top left), FDG, FAP and SSTR2 imaging may be able to identify vulnerable plaque, while CT and MRI can help evaluate degree of stenosis. For evaluation of thrombosis (top right), nuclear imaging may be able to identify early clot formation with radiotracers directed at fibrin or glycoprotein IIb/IIIa, and MRI can use a long inversion time to identify thrombus, as with T1600. For evaluation of cardiomyopathy/myocarditis (middle), echo and MRI can evaluate ejection fraction as well as myocardial strain. For myocarditis, MRI can evaluate tissue characteristics such as T1, T2 and DGE, which are now components of the Lake Louise criteria for myocarditis. Nuclear can evaluate for T cell infiltration using tracers targeting CD4, CD8 cells. Tracers directed against FAP, such as  $^{68}\text{Ga}$ -FAPI has been shown to be increased in an animal model of checkpoint inhibitor myocarditis. Evaluation of pericarditis (bottom left), a complication of checkpoint inhibitors can be assessed by echo for detection of pericardial effusion, but with greater specificity MRI can identify edema and DGE. Atherosclerosis (bottom right) can be evaluated by traditional SPECT and PET techniques to evaluate for perfusion with stress and rest. CT coronary is now first line for evaluation of those with intermediate risk chest pain to rule out obstructive disease. Stress MRI or DGE can also be performed to evaluate for prior myocardial infarction as well as myocardial viability.

or scarring is another tissue characterization parameter that can evaluate for immunotherapy toxicities. MRI is recommended by specialty society guidelines as part of the evaluation and monitoring of ICI myocarditis using the Lake Louise criteria, updated in 2018 to require both increased myocardial signal intensity ratio  $>2$  or increased myocardial relaxation times or visible myocardial edema in T2-weighted images and increased myocardial relaxation times or extracellular volume fraction or DGE in T1-weighted images for the imaging diagnosis of myocarditis (80, 96–100). However, DGE is non-specific and cannot distinguish from cell damage vs. end stage fibrosis and current standard clinical imaging modalities are lacking in assessment of potential molecular correlates, such as collagen deposition and scar. Thus, molecularly targeted imaging tracers may shed light on both mechanism and help increase the specificity of cardiac imaging findings.

## MOLECULAR TARGETED NUCLEAR IMAGING MODALITIES TO EVALUATE ONCOLOGIC THERAPY RELATED ADVERSE CARDIOVASCULAR PATHOLOGIES

### Molecular Nuclear Imaging for Evaluation of Anthracycline Cardiotoxicity

Anthracycline mediated cardiotoxicity has been associated with an increase in reactive oxygen species (ROS) levels in the heart. ROS levels have been shown to confer cardiotoxicity by increased apoptosis, inflammation, mitochondrial dysfunction and activation of matrix metalloproteases (31). Molecular nuclear imaging studies have helped shed light on mechanisms of anthracycline mediated cardiotoxicity. Increased ROS levels in an animal model of doxorubicin cardiotoxicity showed that a novel

PET tracer,  $^{18}\text{F}$ -labeled radioanalog of dihydroethidium, [ $^{18}\text{F}$ ]-6-(4-((1-(2-fluoroethyl)-1H-1,2,3-triazol-4-yl)methoxy)phenyl)-5-methyl-5,6 dihydrophenanthridine-3, 8-diamine ([ $^{18}\text{F}$ ]-DHMT), which targets superoxide, was able to reveal an elevation in superoxide levels in the heart at least 2 weeks prior to a drop in the left ventricular ejection fraction (35). ROS activation of MMPs downstream can then promote adverse cardiac remodeling (101). Renin-angiotensin-aldosterone system (RAAS) activation has been shown to augment the progression of anthracycline induced cardiotoxicity and inhibition *via* RAAS inhibitors like angiotensin receptor blockers or angiotensin converting enzyme inhibitors have been able to prevent and treat anthracycline mediated cardiomyopathy (102, 103). Use of a novel angiotensin receptor-neprilysin Inhibitor, sacubitril/valsartan in a rodent model of anthracycline cardiotoxicity was able to attenuate cardiotoxicity. MMP imaging of activated MMPs using SPECT radiotracer  $^{99\text{m}}\text{Tc}$ -RP805 showed that sacubitril/valsartan in conjunction with doxorubicin was able to significantly attenuate MMP activation as well as prevent a decline in LVEF compared to doxorubicin alone vs. doxorubicin and valsartan groups. Myocardial MMP activity as assessed by  $^{99\text{m}}\text{Tc}$ -RP805 uptake was inversely related to left ventricular ejection fraction (31). In addition to MMP activation and adverse remodeling, ROS can also injure endothelial cells. Anthracycline use has been associated with capillary loss in the heart in some rodent models and protection of endothelial cells with vascular endothelial growth factor-B (VEGF-B) treatment led to preservation of capillary mass (104).

ROS has also been shown to confer mitochondrial dysfunction. Disruption of mitochondrial membrane potential in mitochondrial dysfunction mediated by anthracycline can be evaluated by  $^{68}\text{Ga}$ -Galmydar. In a rodent model, uptake of  $^{68}\text{Ga}$ -Galmydar was reduced by 2-fold with anthracycline treatment compared to control and in H9c2 rat cardiomyoblasts, this was associated with activation of the apoptosis cascade (36).

Early markers of anthracycline cardiotoxicity include an increased uptake of indium-111-labeled antimyosin in the heart, which occurs due to myocyte damage and subsequent association of antimyosin with myosin, which is normally intracellular. Increased uptake of  $^{111}\text{In}$ -antimyosin in patients on anthracycline was associated with LV dysfunction (30). Detection of the earliest stages of apoptosis can also signal early toxicity. Annexin V has a high affinity for phosphatidylserine, which gets exposed on the cell surface during apoptosis. Use of annexin V imaging has allowed for detection of cells undergoing apoptosis. In a rodent model of doxorubicin cardiotoxicity, radiolabeled annexin V,  $^{99\text{m}}\text{Tc}$ -annexin was used to visualize apoptosis that corresponded to histological evidence of apoptosis on TUNEL staining (33). Finally, sympathetic nervous innervation of the myocardium has also been shown to be disrupted with anthracycline toxicity. An assessment of myocardial sympathetic innervation impairment was done by evaluating a radiotracer that is an analog of norepinephrine, iodine-123-labeled meta-iodobenzylguanidine ( $^{123}\text{I}$ -MIBG). A decrease in  $^{123}\text{I}$ -MIBG uptake with increasing cumulative doses of anthracyclines in human patients was associated with LV dysfunction. However, it takes higher cumulative doses of anthracycline to see a drop in

$^{123}\text{I}$ -MIBG uptake, thus this agent would be less useful if earlier detection of toxicity is desired. However,  $^{123}\text{I}$ -MIBG is clinically available and routinely used to evaluate for adrenaline secreting tumors (30) (Figure 2).

## CD4, CD8 Imaging in ICI Myocarditis

Molecularly targeted radiotracers in nuclear medicine are emerging to evaluate processes such as fibrosis, inflammation and thrombosis, extending beyond nuclear cardiology's traditional use to evaluate perfusion deficits in ischemic heart disease *via* single photon emission computed tomography (SPECT) and positron emission tomography (PET), tissue viability or inflammation with PET fluorodeoxyglucose (FDG), which evaluates for glucose uptake predominantly by inflammatory cells, such as myeloid and T cells (106). These processes are common adverse effects of oncologic and immunotherapies.

Detection of the earliest signs of myocardial inflammation in ICI myocarditis, which occurs in 1-2% of patients on these agents remains a clinical challenge (95, 107). The ability to detect the initial infiltration of inflammatory cells such as CD4 or CD8 cells before injury has occurred could help reduce morbidity and high mortality associated with this condition (25). Emerging molecularly targeted probes against CD4,  $^{89}\text{Zr}$ -DFO-CD4 and CD8 cells,  $^{89}\text{Zr}$ -DFO-CD8a may be a potential avenue to detect inflammation at these earliest of stages, which can prompt more frequent follow ups, biomarker checking and earlier therapy (44). Determining specificity of these findings will also be important as to avoid withholding cancer fighting immunotherapy or treatment with steroids, which may potentially lower the efficacy of the immunotherapy agent (108–110). Checkpoint inhibitors have been shown to accelerate atherosclerosis and increase risk of plaque rupture in addition to the risk for myocarditis and pericarditis by driving increased inflammatory cells, including CD8 T cell infiltration into plaques in animal models and patients on checkpoint inhibitors (43, 111, 112). Thus, evaluation of atherosclerotic lesions with CD8 radiotracers, may be able to identify those at risk for myocardial infarction in patients on checkpoint inhibitor therapy.

## Detection of Vulnerable Plaque

Both checkpoint inhibitor use and certain TKIs like ponatinib and sorafenib have been associated with increased risk of myocardial infarction (43, 113). ICIs have also been associated with increased risk of stroke (114). Use of ICIs have been associated with increased infiltration of CD3, CD8 and CD68 cells, markers for T cells and macrophages respectively into atherosclerotic lesions (115). Increased somatostatin receptor 2 (SSTR2) on the cell surface of inflammatory macrophages is a marker of macrophage activation. In a study of symptomatic stroke patients, increased uptake of SSTR2 in culprit vessels assessed by PET tracer  $^{68}\text{Ga}$ -DOTATATE was shown to predict plaque rupture (58). Thus, evaluation of SSTR2 levels in patients on ICI therapy may help identify vulnerable plaques and warrants further investigation. The mechanisms for TKI mediated MI on the other hand are attributed to endothelial cell dysfunction and activation of apoptosis pathways, although direct evidence for MI mechanisms are still lacking, thus further research would be

## Molecular nuclear imaging elucidates anthracycline cardiotoxicity mechanisms

**FIGURE 2 |** Molecular nuclear imaging elucidates anthracycline cardiotoxicity mechanisms. Anthracyclines can increase ROS levels (which can be assessed by nuclear tracer  $^{18}\text{F}$ -DHMT), which can activate MMPs (which can be assessed by  $^{99\text{m}}\text{Tc}$ -RP805) (bottom left), leading to adverse cardiac remodeling. ROS levels can also promote mitochondrial dysfunction, which can disrupt the mitochondrial membrane potential and thereby reduce  $^{68}\text{Ga}$ -Galmydar uptake (middle bottom). Mitochondrial damage can lead to apoptosis, which can be detected by Annexin V positivity (detected by  $^{99\text{m}}\text{Tc}$ -Annexin (bottom right)). Damage to cardiomyocytes can lead to release of intracellular myosin, which can thereby be assessed by (105). In-myosin (right of ROS). In addition to ROS increase, anthracyclines can also directly bind and inhibit Topoisomerase II, which can lead to double-stranded DNA breaks (right) and cause further mitochondrial dysfunction and prevent mitochondrial regeneration. Finally, anthracyclines can lead to impaired sympathetic innervation over time for mechanisms that are unclear but is associated with cardiac dysfunction and this can be assessed by  $^{123}\text{I}$ -MIBG uptake (top left).

needed to see if macrophage activation is involved and whether activated macrophage imaging would help risk stratify patients on these TKIs (113).

### FAP Imaging in ICI Myocarditis

Another potential marker of early stages of ICI myocarditis is fibroblast activating protein (FAP), which is a protein that gets significantly upregulated in cancer tissue, atherosclerosis, arthritis and fibrosis. It is emerging as an imaging marker for fibroblast activation and fibrosis (116, 117). A PET radiotracer targeting FAP is  $^{68}\text{Ga}$ -FAP. In a recent study,  $^{68}\text{Ga}$ -FAP was shown to be a potential early marker of ICI myocarditis with median standardized uptake values (SUV) 1.79 (IQR 1.62, 1.85) in myocarditis patients vs. 1.15 (IQR 0.955, 1.52) in non-myocarditis patients (45). FAP has also been used to evaluate post myocardial infarction fibrosis, but its level in the blood vessels and myocardium of patients on checkpoint inhibitors is unclear (118, 119).

### PD1 Imaging as a Potential Risk Factor for ICI Myocarditis

Another challenge with checkpoint inhibitor myocarditis is trying to figure out who is at increased risk. Programmed cell

death protein 1 (PD1), a target of checkpoint inhibitors like pembrolizumab and its expression on cardiomyocytes warrants additional research as a potential risk factor. PET radiotracer,  $^{64}\text{Cu}$ -DOTA-pembrolizumab can detect PD1 in rodent hearts as well as on the surface of human blood cells and may be used in such an investigation (120).

### MRI DGE Limitations in Fibrosis Assessment and Collagen Imaging

A higher burden of DGE and presumed scarring in hypertrophic cardiomyopathy is associated with worse cardiovascular and death outcomes (121, 122). In a retrospective study of ICI myocarditis patients who underwent cMRI, DGE evaluation did not correlate with cardiovascular outcomes, nor fibrosis, with only 35% of pathology proven fibrosis cases showing DGE on MRI (96, 121, 123, 124). Further, of the 56 patients with histopathology available either through biopsy or autopsy, 98% had lymphocytic infiltration but only 38% had DGE and 26% with T2 positivity (96). Thus in addition to evaluation of lymphocytic infiltration with targeted radiotracers for CD4 and CD8 cells to identify early stages of myocarditis and increase sensitivity of diagnosis, late stages of myocardial injury that can result in scar and thus collagen deposition can be evaluated

by radiotracers targeting collagen. The PET radiotracer  $^{68}\text{Ga}$ -collagen targets collagen, which can help quantify the burden of scarring or end stage fibrosis, which was shown to be able to detect pulmonary fibrosis in a mouse model of bleomycin induced pulmonary fibrosis and correlated with fibrosis on pathology (46) (**Figure 3**). MRI with DGE is able to evaluate for possible scarring, but it is not able to distinguish between early vs. late stage fibrosis, with the former having potential reversibility and may partially explain the differential outcomes we see between HCM and ICI myocarditis patients when it comes to the differences in the fibrosis processes between the two conditions and correlation of scar burden as quantified by DGE and outcomes (125). There is also a MRI collagen type I targeted probe EP-3533 that is conjugated to gadolinium, which was shown to be able to visualize pulmonary, liver and bowel fibrosis in rodent models, but these have not yet advanced to use in humans (126–128).

## Thrombosis Imaging

Pathologic thromboses like pulmonary embolism (PE), deep vein thrombosis (DVT) carries high morbidity and mortality (129). Cancer patients are at increased risk of thrombosis and some of their oncologic therapies can increase that risk further (130, 131). ICI, VEGF inhibitors and lenalidomide have been associated with increased thrombosis risk. Increasing the sensitivity of diagnosing blood clots so treatment can be timely instigated may help avoid complications and help improve outcomes (132–134). Radiotracers that can target fibrin, a molecular precursor of blood clotting can be useful in detection of blood clots. PET radiotracer  $^{64}\text{Cu}$ -FBP8 can target fibrin and has been used to identify thrombi in animal models, particularly earlier stages of clots (49). Another PET radiotracer,  $^{18}\text{F}$ -GP1 that targets the glycoprotein IIb/IIIa receptors on activated platelets and has been demonstrated to detect venous thrombosis and arterial thromboses (53, 135). A phase 1, first-in-human study of  $^{18}\text{F}$ -GP1 positron emission tomography for imaging acute arterial thrombosis is underway (53). These PET thrombosis imaging agents may be of utility for detection of DVTs and PEs in cancer patients, especially for those who may have contraindications to contrast, such as those with chronic kidney disease or those who have an allergy to contrast.

## MOLECULAR MRI AND MR SPECTROSCOPY

### Hyperpolarized MRI for Evaluation of Cardiac Metabolism *in vivo*

As the human heart fails, it has been shown to shift its metabolism from predominantly fatty acid oxidation to more glucose utilization (136). Changes in oxidative phosphorylation or substrate utilization may reflect early signs of cardiotoxicity, yet *in vivo* real time detection of cardiac metabolism has been limited to small studies with radioactive tracers using PET. More recently, substrate utilization and metabolism have been evaluated using magnetic resonance (MR) imaging and spectroscopy. Hyperpolarized carbon-13 ( $^{13}\text{C}$ ) labeled pyruvate

imaging is different from standard clinical MRI using gadolinium contrast, in that it provides information on how tissue uses carbon-based nutrients (37). In rodent models of anthracycline cardiotoxicity, carbon-13 MR spectroscopy (MRS) was used to assess changes to oxidative phosphorylation and tricarboxylic acid (TCA) cycle flux *in vivo*. These studies showed that doxorubicin lead to reduced cardiac oxidative phosphorylation in a rat model as evidenced by increased  $^{13}\text{C}$  lactate production (38). First in human MRS was used to evaluate tumor metabolism in prostate cancer and ongoing clinical trials are evaluating hyperpolarized MR in tumor metabolism and correlations with outcomes in prostate and pancreatic cancer (137–139). First use of hyperpolarized  $^{13}\text{C}$  metabolic MRI in human heart involved evaluation of pyruvate metabolism in healthy individuals (39). Hyperpolarized MR imaging may allow for visualization of changes in cardiac energetics, particularly from fatty acid metabolism to more glucose utilization in an evolving cardiomyopathy in response to cardiotoxic chemotherapy and to evaluate response to cardioprotective medications such as beta blockers and angiotensin converting enzyme inhibitors in real time (140).

### Apoptosis Evaluation by MRI

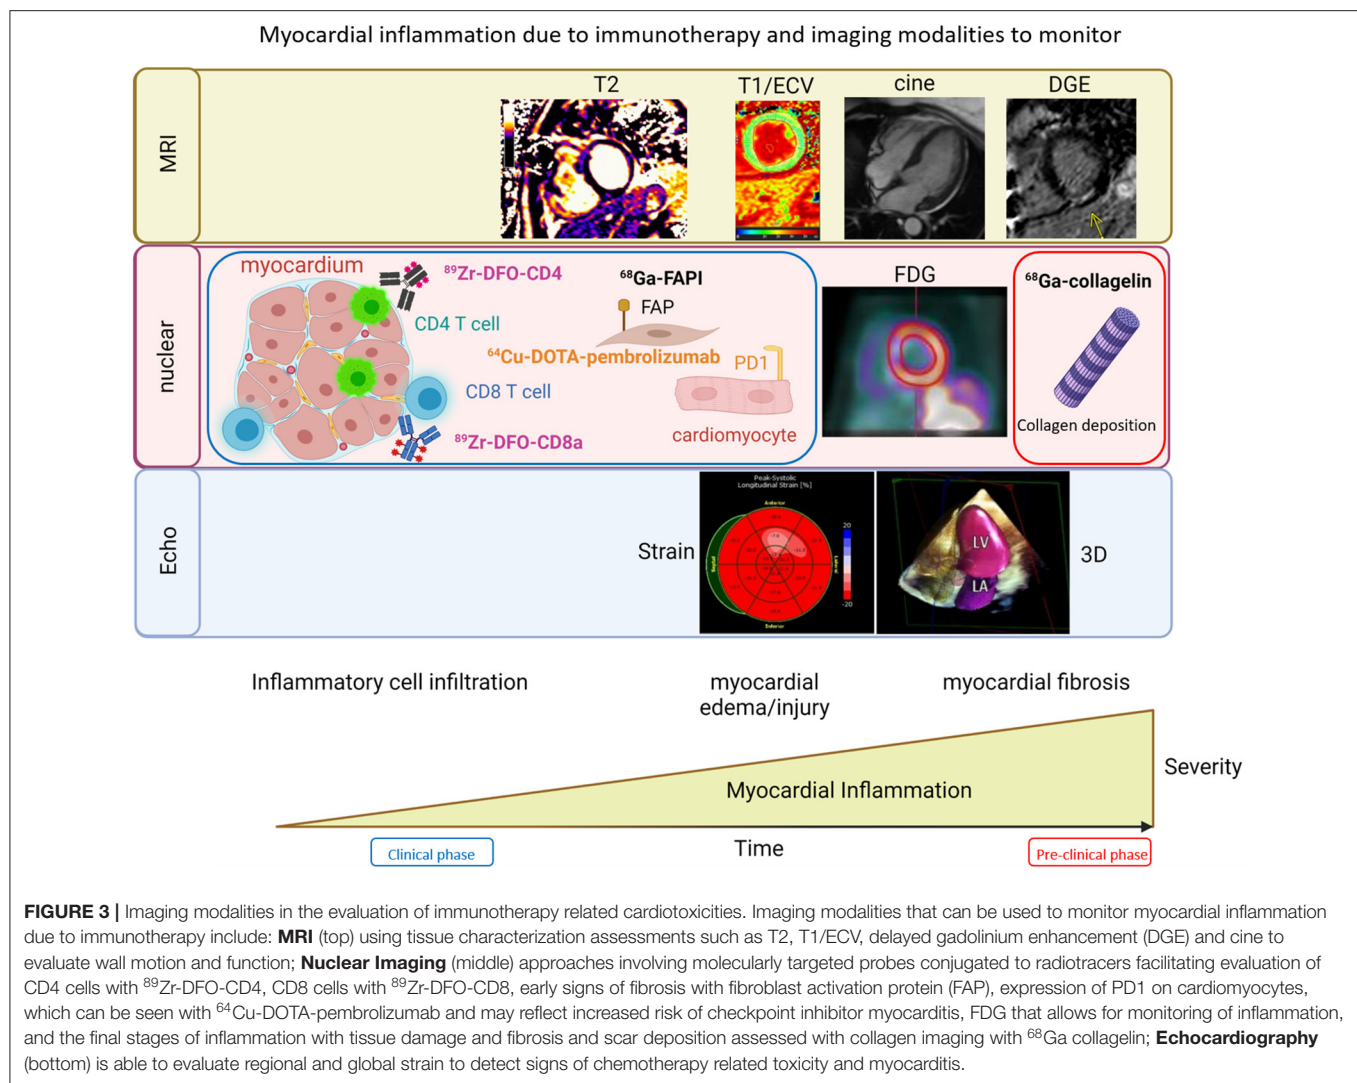

Various chemotherapy agents, most notably anthracyclines are known to increase cardiomyocyte apoptosis. Molecular MRI probes conjugated to superparamagnetic iron oxide (SPIO) and human annexin was shown to be able to visualize apoptosis in real time in a rodent model following ischemia and post doxorubicin exposure, but these MRI molecular probes have not gone beyond animal studies thus far but have the potential to detect early signs of cell death in the myocardium (105, 141).

### Inflammation Imaging by MRI

In addition to T1, ECV and T2 signal changes, use of ultrasmall superparamagnetic particles of iron oxide (USPIOs) in MRI may confer insights on inflammation *via* increased macrophage activity. USPIOs have been shown to be taken up by macrophages and correlates with plaque inflammation in animal studies (142). In a study of patients with severe carotid stenosis, uptake of USPIOs corresponded to inflamed plaques on histology. Uptake of USPIOs induced areas of signal loss on T<sub>2</sub>\*-weighted magnetic resonance imaging within the vessel wall. Whether this can help predict plaque vulnerability in those on checkpoint inhibitors or help identify ICI myocarditis is untested and warrants further investigation (143). However, this has been used clinically and may have potential to distinguish vulnerable plaque from less vulnerable plaque.

### Barriers to Advancing Molecular Imaging

For the molecular imaging tracers that are already clinically used, barriers to use include radiation exposure, so deciding who should get the test, when to get it and how often will have to be established. For example, if FAP is associated with ICI myocarditis as a potential early marker, then perhaps it should be obtained when there is suspicion for myocarditis or when troponin becomes positive. Timed with evaluation of this marker for residual disease, it can also help with monitoring of resolution

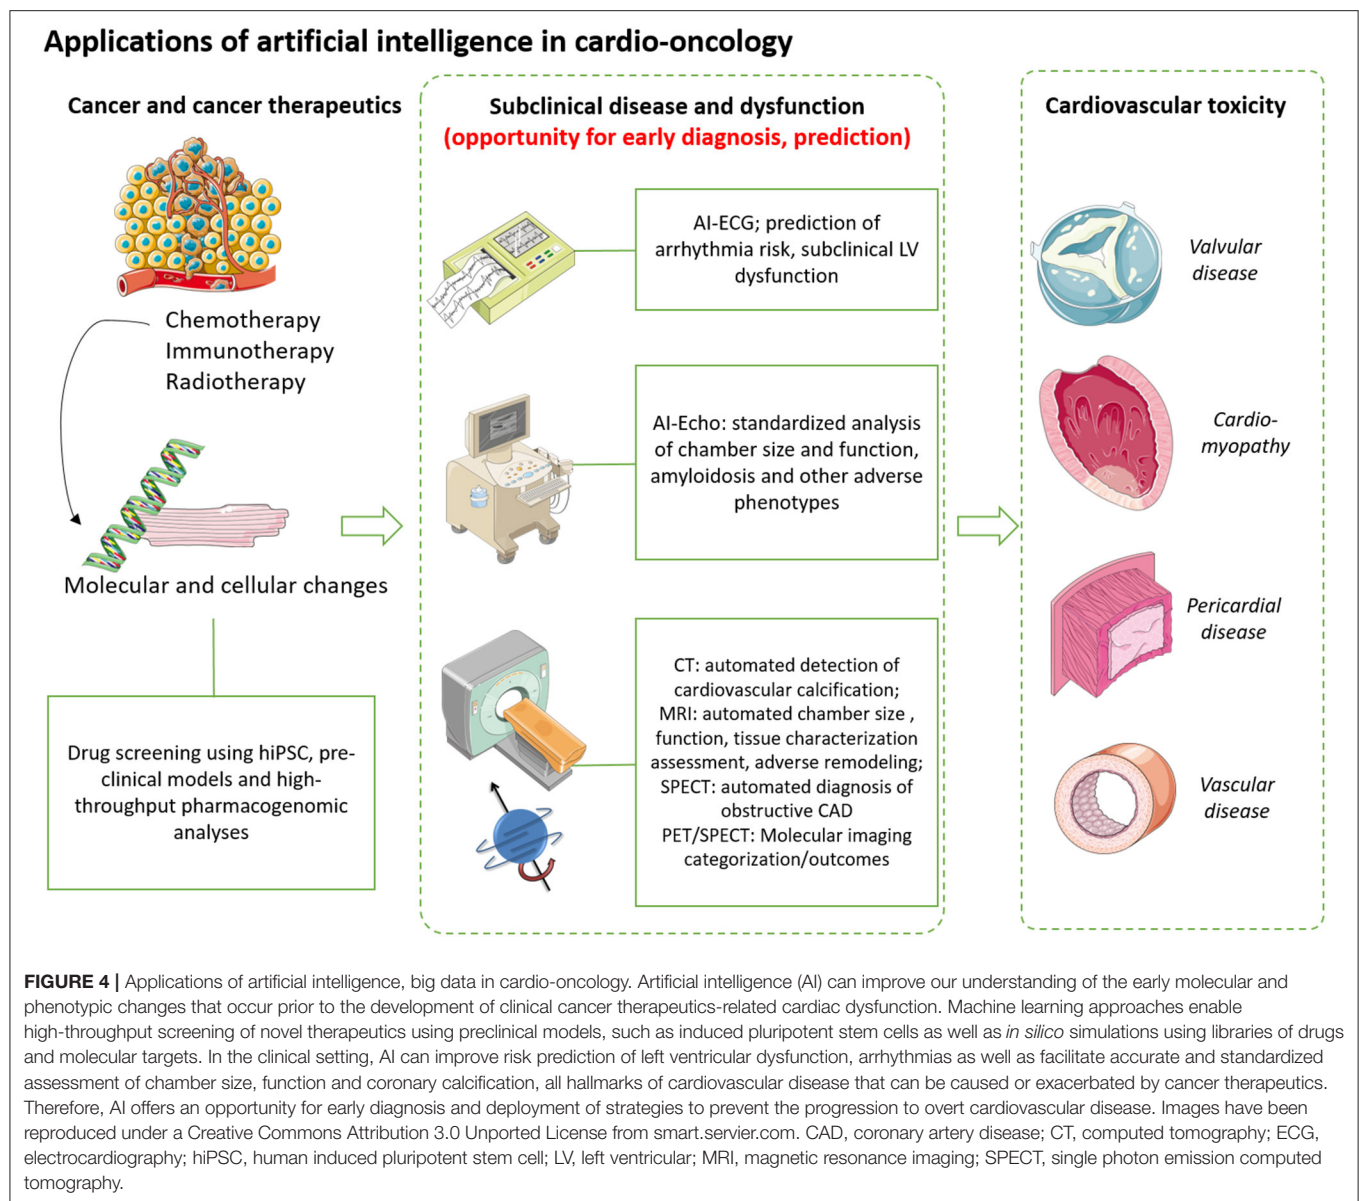

of myocarditis, potentially complementing cardiac MRI or taking place of MRI for those who cannot tolerate MRI, which is usually used for monitoring. Access is another challenge. Access to molecular nuclear studies are often available through large hospital systems and for agents with shorter radioisotope half-lives like Gallium-68 ( $^{68}\text{Ga}$ ) with average half-life of 68 min, an onsite germanium-68/gallium-68 generator is needed along with accompanying nuclear accreditation, thus, more rural hospitals or private practices may have to refer out to larger centers in order to obtain these tests at high volume imaging centers (144). Finally, nuclear studies tend to be more expensive than echo and either on par or more expensive than MRI studies due to the costs associated with radiolabeled probes, thus being able to get these studies approved can also be a challenge for providers even if it is clinically used and indicated. For the molecular tracers that are in the preclinical stage, the usual barriers exist for clinical translation, including establishing safety, a favorable target to noise ratio in humans and correlation with outcomes to achieve FDA approval and ultimately clinical use. For those radiotracers that are already in clinical use for oncology indications, such

as FAP, CD4, CD8 and PD1, incidental detection in the heart and correlation with outcomes is possible and can be further explored for future dedicated cardiac imaging and may provide unique clinical value. The power of machine learning, artificial intelligence and big data in evaluation of imaging signals can help unlock patterns that humans may not readily be able to see, such as in a recent evaluation of cardiac fibrosis by T1 imaging by MRI and be able to correlate these imaging findings with outcomes (145).

## ROLE OF ARTIFICIAL INTELLIGENCE (AI) AND BIG DATA IN CARDIO-ONCOLOGY AND IMAGING

### Overview of Current AI Applications in Cardio-Oncology

Artificial intelligence (AI), through the training of machine and deep learning models, has shown remarkable potential in the prevention and diagnosis of cancer therapeutics-related

cardiac dysfunction (CTRCD). With applications across all stages of the natural history of CTRCD, AI can assist scientists and physicians in screening for molecular interactions between novel therapeutic agents and the cardiovascular system, as well as detecting subclinical cardiovascular effects prior to the development of overt clinical disease (Figure 4).

At the pre-clinical stage, AI techniques have been used for high-throughput screening of cancer agents using a variety of disease models. These range from human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) exposed to antineoplastic agents, screening of drug libraries to detect agents that interact with channel proteins resulting in QT prolongation, all the way to exome sequencing to identify variants in cardiac injury pathway genes that protect against anthracycline-induced cardiotoxicity and dual transcriptomic and molecular machine

learning to predict different types of cardiotoxic response (146–150). Such approaches can de-risk early-stage drug discovery but also contribute to post-marketing surveillance to maximize patient safety. On the same note, pharmacovigilance in cardio-oncology can be assisted by machine learning-guided monitoring of electronic health records that includes patient demographics, echocardiography, laboratory values to detect signals suggestive of increased cardiac risk with specific therapies or practices (151, 152).

For therapies that form the mainstay of cancer therapy, ranging from chemotherapy to immunotherapy and radiation therapy, active surveillance protocols have been proposed and implemented, particularly for therapies with known cardiotoxic effects, such as anthracyclines and HER-2/neu inhibitors. Here, non-invasive cardiac imaging (by means of transthoracic echocardiography and/or magnetic resonance

imaging (MRI)) and electrocardiography (ECG) represent the modalities of choice in the screening of conditions, such as anthracycline-induced cardiotoxicity and immune checkpoint-induced myocarditis (78, 153). Whereas AI applications in cardiovascular imaging have traditionally been developed in the general population, shared phenotypes seen in both CTRCD and non-cancer-related cardiac dysfunction, may extend the use of these technologies to cardio-oncology.

An expanding body of research has in fact demonstrated the ability of deep learning-enhanced interpretation of ECG in screening for and improving the diagnosis of left ventricular dysfunction, essentially functioning as a gatekeeper to the use of more advanced imaging modalities (154). It is notable that this tool was tested in a randomized controlled trial and demonstrated effectiveness in increasing the early diagnosis of decreased left ventricular ejection fraction (LVEF) without an increase in the use of echocardiography (155). Similarly, AI-guided ECG assessment can also predict the future incidence of atrial fibrillation (156). In childhood cancer survivors, machine learning algorithms of baseline and follow up ECGs were able to predict future cardiomyopathy (157). However, whether these results generalize to cardio-oncology, such as in the monitoring of anthracycline or Herceptin mediated cardiotoxicity, or ibrutinib-associated atrial fibrillation remains unknown and should be explored in future studies (158, 159).

AI has contributed to a more efficient and standardized interpretation of several non-invasive cardiovascular imaging modalities. For instance, in the field of transthoracic echocardiography, deep learning video-based models now enables fast and automated calculation of LVEF, with variance that is comparable to that or even lower of a human observer (160, 161). Similarly, combined assessment of ECG- and echocardiography-derived AI models has shown good discrimination in detecting cardiac amyloidosis, a rare disorder that is however more prevalent among patients with cancer compared to the general population (162). Similar approaches can be found in the field of computed tomography (CT) imaging, where automated tools enable an accurate assessment of coronary artery calcium burden, which can be generalized to both gated and non-gated CT scans of the chest, with the latter often used in the staging or monitoring of patients (163, 164). Therefore, such tools may refine a patient's baseline cardiovascular risk and inform risk-benefit discussions about the deployment of potentially cardiotoxic therapies. Finally, automated chamber size quantification, tissue characterization parameters such as T1, T2, extracellular volume and functional indices that can be extracted from cardiac MRI images can have the ability to confer insights into cardiotoxicity including the potential to identify early to late cardiotoxicity mediated by chemotherapy or immunotherapy agents *via* detection of changes in chamber size, abnormal T1, T2 relaxation times and delayed gadolinium enhancement patterns (86, 95, 96, 99, 145, 165–167). Deep learning models have also shown promise in the standardized interpretation of functional nuclear modalities, such as SPECT (single photon emissions computed tomography) myocardial perfusion imaging with good discrimination for the presence of obstructive coronary artery disease (168). However, as these tools

become clinically available, prospective validation and possibly recalibration specifically in patients with cancer will be required to ensure their validity and generalizability.

## Strengths and Weaknesses of Current Methods and Barriers for Clinical Translation

To better understand the strengths and weaknesses of AI applications in cardio-oncology, one first needs to review key definitions. AI refers to the ability of an automated system to perform tasks that are typically characteristic of human intelligence, such as image and pattern recognition, as well as prediction and classification. *Machine learning* describes the process by which a system gains the ability to perform such tasks. This learning process can be further divided into *supervised* and *unsupervised learning*. The former describes the analysis of labeled datasets with the goal of predicting the label of a given datapoint based on a set of independent predictors. The latter refers to the analysis of unlabeled and unclassified datasets where the algorithm attempts to discover patterns within the data on its own. Algorithms may range from traditional regression models to deep neural networks, consisting of multiple layers of neurons and nodes which operate in a manner similar to the human brain (169, 170). However, independent of the algorithm used, machine learning systems rely on high-quality input to deliver high-quality output. This is where “big data” become relevant, describing the need for datasets that are large enough to ensure adequate variance, remain representative of their original and target populations, enable time-efficient analyses and have been carefully rather opportunistically curated to address a specific question (171).

With those key concepts in mind, some of the limitations of machine learning applications in cardio-oncology become apparent. First, cardiovascular disease is often listed as an exclusion criterion in major cancer trials, thus resulting in under-representation of patients with cardiovascular disease in pivotal cancer trials (172). However, the inclusion of cardiovascular outcomes in cancer trials will be able to help fill this data gap if sufficient baseline and follow up data are acquired (molecular biomarkers, baseline imaging prior to oncologic therapy and follow up that can be used as input). Second, while AI systems can learn patterns in the data, explaining what drives those predictions or establishing causal inference is not a straightforward task (173). Moreover, cancer is a highly heterogeneous condition with multiple molecular, histological, and clinical subtypes that often respond differently to the same therapies (174). Therefore, ensuring generalizability of models across different cancer subtypes, treatments and patient populations may be an insurmountable task without access to vast amounts of accurately labeled data. Third, there is often significant delay in the timing between data collection, model training and the final model deployment. As a result, AI models are often outdated when deployed for clinical use, thus highlighting the need for more efficient pathways that would enable real-time updates. Finally, AI models are bias-prone often reproducing biases that are inherently present in the datasets

used for training. Ensuring representation of diverse patient populations is of paramount importance to promote an equitable impact of AI in healthcare delivery and outcomes (175).

## Future Applications of AI in Cardio-Oncology and Molecular Imaging

With careful consideration of these limitations, AI has the potential to advance cardio-oncology in many different directions. Radiomic applications, which extract several metrics based on the shape, dimensions, signal density and spatial interrelationship of voxel signals in a given tissue, have been found to be superior to conventional readouts in reflecting tissue composition, as well as metabolic or inflammatory activity (176–178). In fact, some of the most exciting applications of AI lie beyond structural imaging in molecular imaging. In the recent past, deep learning and generative adversarial networks have successfully reconstructed PET images directly from raw sinogram data effectively maximizing image quality (179, 180). In other applications, AI tools have generated full-dose PET images from low-dose images, thus maximizing signal-to-noise ratio at lower radiation levels (181, 182). In another example, convolutional neural networks have enabled the development of cMRI virtual native imaging technologies which generate late gadolinium enhancement-like images in an accurate and reproducible manner without the need for contrast administration (183). Though originally developed in patients with hypertrophic cardiomyopathy, this technology may be of value in cardio-oncology and the monitoring of ICI-myocarditis. Further, for molecular imaging targeting biomarkers like FAP and PD1, these are already used clinically in oncology to monitor for residual disease and assess response to immunotherapy respectively, thus if the heart is captured in existing data sets, AI/ML can help to predict whether the presence of these markers are associated with adverse cardiovascular outcomes. Coupled with improvements in the speed and accuracy of segmentation algorithms, AI can accelerate the clinical deployment of molecular imaging approaches in the timely detection of cardiovascular toxicity (184).

## CONCLUSIONS

Imaging advances, particularly molecularly targeted imaging modalities may help detect cardiotoxicities at the earliest stages with greater specificity, shed light on mechanism as well as response to cardioprotective medications such as beta blockers, angiotensin converting enzyme inhibitors, etc. Newer MRI metabolic evaluation techniques such as hyperpolarized MRI may allow for a non-invasive approach to evaluate cardiac metabolism in real time. To complement imaging studies, use of AI and big data on imaging parameters and forthcoming molecular imaging datasets, in addition to patient demographics may help predict or detect cardiovascular toxicities at their earliest stages. Inclusion of diverse patient cohorts as well as cardiovascular parameters/biomarkers and imaging in cancer trials can enable AI/ML to increase accurate categorization as well prediction models in cardio-oncology patients. Additional research in these areas and advancing animal studies toward human studies may further help improve cardiovascular outcomes in cancer patients.

**Background:** N<sup>6</sup>-methyladenosine (m<sup>6</sup>A) plays important roles in various cardiovascular diseases (CVDs), including cardiac hypertrophy and heart failure. Sunitinib (SUN) is a tyrosine kinase inhibitor (TKI) that is widely used in the treatment of different types of solid and blood tumors, but its efficacy is restricted by a concomitant rise in cardiotoxicities. However, the methylation modification of m<sup>6</sup>A messenger RNA (mRNA) in cardiomyocytes treated with TKI has not been investigated.

**Methods:** The global m<sup>6</sup>A methylation level of SUN-induced cardiotoxicity was detected by m<sup>6</sup>A dot blot and colorimetric methylation assay. MeRIP-Seq (methylated RNA immunoprecipitation sequencing) and RNA-seq (RNA sequencing, input) were employed to depict the landscapes of transcriptome and epitranscriptome in TKI. Changes in major m<sup>6</sup>A-related enzymes were detected by qRT-PCR and Western blot. In addition, the effects of FTO on SUN-induced cardiotoxicity were evaluated by gain and loss of function studies.

**Results:** In this study, we observed that the m<sup>6</sup>A methylation level was significantly elevated in SUN-treated human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) and paralleled a positively correlated cellular damage level. Through a genome-wide analysis of m<sup>6</sup>A mRNA methylation by methylated RNA immunoprecipitation sequencing (MeRIP-seq) and input RNA sequencing (RNA-seq), we identified a total of 2,614 peaks with significant changes, of which 1,695 peaks were significantly upregulated and 919 peaks were significantly downregulated. Quantitative reverse transcription PCR (RT-qPCR), immunofluorescence, and Western blotting revealed that the RNA demethylase fat mass and obesity-associated protein (FTO) was downregulated, whereas the RNA methylases methyltransferase-like 14 (METTL14) and wilms' tumor 1-associating protein (WTAP) were upregulated. Furthermore, gain- and loss-of-function studies substantiated that FTO is cardioprotective in TKI.

**Conclusion:** This study deciphered the methylation modification of m<sup>6</sup>A mRNA in hiPSC-CMs post-TKI treatment and determined that FTO may be a promising therapeutic target for TKI-induced cardiotoxicity.

**Keywords:** tyrosine kinase inhibitor (TKI), hiPSC-CMs, N<sup>6</sup>-methyladenosine, FTO, cardiotoxicity

## INTRODUCTION

Tyrosine kinase inhibitors (TKIs) have been widely used in the treatment of various types of cancer, some of which are in different stages of clinical development, which shows the importance of tyrosine kinase as the main target of new antitumor drugs (1). However, the widespread use of TKIs was restricted due to their cardiovascular toxicity, which threatened patients' medication compliance and quality of life (2). Therefore, the study of the cardiovascular toxicity mechanism of TKIs is of great significance for circumventing these cardiovascular complications. Sunitinib (SUN), a small-molecule, multitarget receptor tyrosine kinase (RTK) inhibitor, was approved by the US Food and Drug Administration (FDA) in 2006 to treat kidney cancer, gastrointestinal stromal tumors, and endocrine tumors (3). Its targets include vascular endothelial growth factor receptors (VEGFRs), platelet-derived growth factor (PDGFR), and mast/stem cell growth factor receptor (SCFR) (4). In the cardiovascular system, SUN impairs cell signal transduction, cell cycle regulation, and cell metabolism, increasing the incidence of cardiac events in patients with cancer (5). However, cardioprotective strategies based on these mechanisms are controversial and have not been proven in humans, suggesting that SUN-mediated cardiotoxicity may also be mediated by other mechanisms (6).

Ribonucleic acid methylation constitutes more than 60% of all the RNA modifications and N<sup>6</sup>-methyladenosine (m<sup>6</sup>A) is the most prevalent RNA modification in mammalian mRNA and long non-coding RNAs (lncRNAs) (7, 8). The m<sup>6</sup>A modification mainly occurs on adenine in the "RRACH" motif and its state is tightly controlled by "writer" methyltransferases (methyltransferase-like 3 (METTL3), methyltransferase-like 14 (METTL14), and Wilms' tumor 1-associating protein (WTAP)), "eraser" demethylases [fat mass and obesity-associated protein (FTO) and Alk B homologue 5 (ALKBH5)], and "reader" m<sup>6</sup>A binding proteins (YT homology domain containing1 (YTHDC1), YTHDC2, YT homology domain family (YTHDF1), YTHDF2, YTHDF3, heterogeneous nuclear ribonucleoprotein C (HNRNPC), heterogeneous nuclear ribonucleoprotein A2B1 (HNRNPA2B1), eukaryotic initiation factor 3A (EIF3A), and EIF3C) (9, 10). Ample evidence suggests that m<sup>6</sup>A modification regulates a variety of RNA metabolic processes, such as mRNA stability, splicing, nuclear transport, and translation capabilities (11–13). Given the importance of m<sup>6</sup>A modification in RNA metabolism, we were, thus, curious to discover whether m<sup>6</sup>A modification had potential effects on TKI-induced cardiotoxicity.

**Abbreviations:** METTL14, methyltransferase-like 14; WTAP, Wilms' tumor 1-associating protein; ALKBH5, Alk B homologue 5; YTHDF, CYT homology domain family; HNRNPC, heterogeneous nuclear ribonucleoprotein C; HNRNPA2B1, heterogeneous nuclear ribonucleoprotein A2B1; EIF3A, eukaryotic initiation factor 3A; RPMI, Roswell Park Memorial Institute; IWR-1, Wnt/β-catenin inhibitor; FB23-2, FTO Demethylase inhibitor; RIPA, Radio-Immunoprecipitation Assay; PVDF, poly vinylidene fluoride; TBST, Tris-Buffered Saline and Tween; ECL, enhanced chemiluminescence; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; DTT, DL-Dithiothreitol; MIT, Massachusetts Institute of Technology; AAV9, adeno-associated virus 9.

Furthermore, previous studies have proposed a cardioprotective role of m<sup>6</sup>A demethylase FTO-mediated demethylating effects in various cardiovascular pathologies. First, reduced FTO expression was observed in failing human hearts and hypoxic cardiomyocytes, thereby increasing m<sup>6</sup>A in RNA and deteriorating cardiomyocyte contractile dysfunction via regulating the methylation of cardiac contractile transcripts (7). Moreover, elevated m<sup>6</sup>A-RNA methylation and FTO repression were causatively involved in myocardial inflammation and dysfunction during endotoxemia in mice (14). Another study showed that FTO overexpression mitigated apoptosis of hypoxia-/reoxygenation-treated myocardial cells by demethylating Mhrt (15). However, the role of FTO in TKI-induced myocardial injury remains to be further revealed.

In this study, we used methylated RNA immunoprecipitation sequencing (MeRIP-seq) and input RNA sequencing (RNA-seq) to study the transcriptome and m<sup>6</sup>A modification epitranscriptome in human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) treated with SUN. To gain further insights into the pathological significance of m<sup>6</sup>A modification in TKI-induced cardiotoxicity, the Gene Ontology (GO) and the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses were performed on the key genes identified by MeRIP-seq and input RNA-seq. Furthermore, we revealed a cardioprotective role of FTO in SUN-treated hiPSC-CMs. This study is the first study to show that m<sup>6</sup>A methylation may play an indispensable role in TKI-induced cardiotoxicity.

## MATERIALS AND METHODS

### Cell Culture

Urinary epithelial cell-derived hiPSCs were cultured in Matrigel (Invitrogen, Carlsbad, California, USA)-coated 6-well plates in E8 medium (Invitrogen, Carlsbad, California, USA) containing 0.5% penicillin/streptomycin. HiPSCs were induced to differentiate into cardiomyocytes when cultured at 80% confluence, as previously reported (16, 17). In short, cells were treated with 6 μM of selective inhibition CHIR99021, a selective inhibitor of glycogen synthase kinase 3β, in Roswell Park Memorial Institute (RPMI) medium supplemented with B27 (Invitrogen, Carlsbad, California, USA) for 48 h, followed by 5 μM of Wnt/β-catenin inhibitor (IWR-1), a Wnt antagonist (Sigma-Aldrich), for another 48 h, and the medium was changed every 3 days. On the 10th day, the beating cardiomyocytes were purified by the glucose starvation method for 5 days for further tests.

### Isolation and Culture of Cardiac Microvascular Endothelial Cells (CMECs) and Cardiac Fibroblasts (CFs)

Primary CMECs and CFs were isolated, cultured, characterized, and subjected to subsequent experiments, as previously reported (18, 19).

### Silence and Overexpression of FTO

We employed commercially available ready-to-use lentiviral constructs pLenti-GIII-CMV (Applied Biological Materials

Incorporation, CAT. NO 210500610196) and FTO small hairpin RNA (shRNA) lentiviral particles (Santa Cruz Biotechnology Incorporation, CAT. NO sc-75002-V) to overexpress or knockdown FTO in hiPSC-CMs. The transfection process was done as per the manufacturer's instructions. Lentivirus particles were transfected at a multiplicity of infection (MOI) of 20.

## Cell Viability Assay

Cell viability was detected with a Cell Counting Kit-8 (CCK-8) (C0037, Beyotime, Shanghai, China). The culture medium was aspirated and the precoated Matrigel hiPSC-CMs were washed with phosphate-buffered saline (PBS) once. Then, 100  $\mu$ l of working buffer was added to hiPSC-CMs in 96-well plates and the cells were incubated at 37°C for 30 min in the dark. A microplate reader (Tecan, Switzerland) was used to automatically measure the absorbance at a wavelength of 450 nm.

## Drug Treatment

Our preliminary results showed that the half-maximal inhibitory concentration (IC<sub>50</sub>) of SUN treatment for 24 h (cell viability serving as the readout) is around 6  $\mu$ M (**Supplementary Figure S1A**); thus, the subsequent experiments were carried out with 6  $\mu$ M SUN (SU11248, Selleck, Shanghai, China) treatment for 24 h and equal volume of dimethyl sulfoxide (DMSO) treatment for 24 h served as the control group. For FTO Demethylase inhibitor (FB23-2) (S8837, Selleck, Shanghai, China) treatment, 20  $\mu$ M FB23-2 was added simultaneously with SUN for 24 h. The concentration of FB23-2 was chosen based on a previous report (20).

## Western Blot Analysis

Cell protein was extracted with Radio-Immunoprecipitation Assay (RIPA) Lysis Solution (P0013C, Beyotime, Shanghai, China) from hiPSC-CMs for Western blot detection. Protein extractions and molecular weight standards were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) gels and transferred to poly vinylidene fluoride (PVDF) membranes (Bio-Rad, USA). After blocking, the membrane was incubated with primary antibodies [methyltransferase-like 3, (METTL3) ab195352, Abcam; METTL14, ab220030, Abcam; FTO, ab126605, Abcam; ALKBH5 aa302-330, LifeSpan Biosciences; WTAP, 56501, Cell Signaling Technology; and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) ab8245, Abcam] at 4°C overnight in a 5% bovine serum albumin (BSA) blocking solution. After being washed with Tris-Buffered Saline and Tween (TBST) buffer, the membrane was incubated in 5% blocking buffer for 1 h at room temperature with the secondary antibody (1:800 dilution, 7074, Cell Signaling Technology, USA) at the recommended dilution. Protein bands were detected with the enhanced chemiluminescence (ECL) chemiluminescent kit (P0018S, Beyotime, Shanghai, China) in a dark room and assessed with Image Lab software (Bio-Rad, USA).

## N<sup>6</sup>-Methyladenosine Dot Blot

The mRNA was isolated with the Dynabeads<sup>®</sup> mRNA Purification Kit (61006, Invitrogen, Carlsbad, California,

USA) and the purity of mRNA was detected by the NanoDrop method for further tests. The serially diluted mRNA was denatured at a high temperature of 95°C and cooled immediately after denaturation. The 2  $\mu$ l sample was transferred directly onto a nucleic acid-optimized nylon membrane (1620153, Bio-Rad, USA). After a regimen UV cross-linking and methylene blue (M4591, Sigma-Aldrich, USA) staining, the membrane was blocked by soaking in 5% BSA buffer and incubated with the anti-m<sup>6</sup>A antibody (ab284130, Abcam, Shanghai, China) in 5% BSA for 30 min at room temperature. Then, the membrane was incubated with horseradish peroxidase (HRP)-conjugated secondary antibody (ab97051, Abcam, Shanghai, China) for 30 min, followed by incubation with the ECL reagent (P0018S, Beyotime, Shanghai, China) for 1 min, covered with plastic wrap, and exposed to different lengths of exposure in a dark room. The test sample was compared with the signal of the standard sample to detect its concentration.

## m<sup>6</sup>A RNA Methylation Assay (Colorimetric)

The m<sup>6</sup>A RNA Methylation Assay Kit (ab185912, Abcam, Shanghai, China) was used to measure the m<sup>6</sup>A level of mRNA. According to the instructions, 80  $\mu$ l of binding solution was added to each well and negative control, diluted positive control, and 200 ng of mRNA were added to each well and incubated at 37°C for 90 min. Fifty microliter of diluted capture antibody was added for incubation at room temperature for 60 min and then 50  $\mu$ l of diluted detection antibody was added to each well for 30 min. Finally, 100  $\mu$ l of developing solution was used for the reaction and after incubation in the dark at room temperature for 10 min, stop solution was added and the absorbance was measured at 450 nm.

## Lactate Dehydrogenase (LDH) Release

The LDH Release Detection Kit (C0016, Beyotime, Shanghai, China) was used to detect cell cytotoxicity according to the instructions. Sixty microliter of LDH detection working solution was added to each well. The sample was incubated at room temperature (~25°C) in the dark for 30 min. Then, the absorbance was measured at 490 nm.

## Quantitative Reverse Transcription PCR (RT-qPCR)

Total RNA was extracted from hiPSC-CMs using the RNAsimple Total RNA Kit (DP419, Tiangen, Beijing, China). One microgram of total RNA was used for complementary DNA (cDNA) synthesis reaction, as previously described (21). The isolated mRNA was reverse transcribed into cDNA with the High Capacity cDNA Reverse Transcription Kit (4368814, Invitrogen, Carlsbad, California, USA) and cDNA was amplified with the Takara's Perfect Real-Time PCR Kit (RR037A, Takara Bio, Otsu, Japan). The primers and probes were ordered from TaqMan (Invitrogen, Carlsbad, California, USA). The relative level of each mRNA was quantified by GAPDH and expressed as a relative ratio.

## Methylated RNA Immunoprecipitation Sequencing

Guangzhou Epibiotek Corporation Ltd. (Guangzhou, China) provided the MeRIP-seq service. Briefly, m<sup>6</sup>A RNA immunoprecipitation was performed with the GenSeq™ m<sup>6</sup>A RNA IP Kit (GE-ET-001, GenSeq Incorporation, China) according to the manufacturer's instructions. Both the input samples were obtained by ribosomal RNA (rRNA) removal and smart principles and first-strand cDNA PCR-enriched library fragments were synthesized. The magnetic bead library fragments were purified by DNA and the ultrafine RNA methylated m<sup>6</sup>A detection library was obtained. The library quality was evaluated using the Bioptic Qsep100 Analyzer (Agilent Technologies Incorporation, USA). Library sequencing was performed on an Illumina HiSeq instrument in PE150 sequencing mode.

## Methylated RNA Immunoprecipitation Sequencing Data Processing

Cutadapt (version 2.5) was used to trim adapters and filter for sequences. The remaining reads were then aligned to the human Ensemble genome GRCh38 (mouse Ensemble genome GRCm38) using Hisat2 aligner (version 2.1.0) under the following parameters: “-rna-strandness RF.” m<sup>6</sup>A peaks were identified using the exome Peak R package (version 2.13.2) under the parameter: “peak\_cutoff\_p-value = 0.05, peak\_cutoff\_false discovery rate (FDR) = NA, and fragment\_length = 200.”

Differential m<sup>6</sup>A peaks were identified using the exome Peak R package under the following parameters: “peak\_cutoff\_p-value = 0.05, peak\_cutoff\_FDR = NA, and fragment\_length = 200.” The GO and the KEGG analyses were performed using the cluster profile R package (version 3.6.0). m<sup>6</sup>A RNA-related genomic features were visualized using the Guitar R package (version 1.16.0). Identified m<sup>6</sup>A peaks with p-values < 0.05 were chosen for the *de-novo* motif analysis using homer (version 4.10.4) under the parameter “-len 6-rna.”

## Long RNA-seq

The Epi™ Mini LongRNA-SEQ Kit (E1802, Epibiotek, Guangzhou, China) and the Epi™ DNA Clean Beads Kit (R1809, Epibiotek, Guangzhou, China) was used for long RNA sequencing. DNase I was added to the RNA samples and digested at 37°C for 30 min to remove the residual DNA in the samples and the RNA was purified and recovered by magnetic beads. rRNA removal and RNA fragmentation: 5XRT buffer was added to sample RNA, a rRNA probe, and a temperature gradient reaction was used to fragment RNA samples and remove rRNA. Synthesis of first-strand cDNA: EpiScript™ IV, RNase inhibitor, DL-Dithiothreitol (DTT), Template-Switching oligonucleotide (TSO), and random primers were added to the RNA samples in Step 2. After mixing with the wall of the tube, rapid centrifugation was carried out in the PCR machine according to the following procedures: 37°C, 90 min; 70°C, 15 min. 2XpfuMax HiFi PCR ProMix and sequencing primers were added to the first-strand cDNA samples and then amplified in a PCR apparatus after mixing. The Epi™ DNA Clean Beads were used to purify PCR products in a 1X ratio. DNA fragments (300–400 bp) were recovered from the purified products with magnetic beads in a 0.65/0.2X ratio for a second round of PCR amplification to enrich

300–400 bp DNA fragments. The Bioptic Qsep100 Analyzer was used to conduct quality inspection of the library to detect whether the size distribution of the library conformed to the theoretical size.

## Ribonucleic Acid Sequencing Data Processing

Cutadapt (version 2.5) was used to trim adapters and filter for sequences and the remaining reads were then aligned to the human Ensemble genome GRCh38 (mouse Ensemble genome GRCm38) using Hisat2 aligner (version 2.1.0) under the parameter “-rna-strandness RF.” The reads mapping the genome were calculated using feature counts (version 1.6.3). Differential gene expression analysis was performed using the DESeq2 R package. Enrichment analysis was performed using the clusterProfiler R package for the GO terms and the KEGG database pathways.

## Immunostaining and Immunofluorescence Analysis

Human-induced pluripotent stem cell-derived cardiomyocytes were separated and placed in 6-well plates (Corning, New York, USA). The combined staining of  $\alpha$ -actinin (ab137346, Abcam), immunoglobulin G (IgG) H&L (Alexa Fluor® 488) (ab150077, Abcam), and propidium iodide (PI) 1  $\mu$ g/ml (ST511, Beyotime, Shanghai, China) was used to detect cardiomyocyte death. The nucleus was stained with 4',6-diamidino-2-phenylindole (DAPI) (C1002, Beyotime, Shanghai China) and the dead cells were labeled with PI to pass through the damaged cell membrane. A Nikon A1R HD25 confocal microscope was used to capture images. The total number of cells in the PI-positive and five randomly selected fields was counted using ImageJ software by a researcher blinded to the treatment assignments. A manual pipeline (CellProfiler, Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard in Cambridge) was used to determine the cell surface area (22). Briefly, 5 to 6 random pictures were taken with 20X magnification and 150–200 cells/per condition were analyzed in order to determine cell size following the instructions of the software.

## Statistical Analyses

Continuous data are expressed as the mean  $\pm$  SD unless otherwise specified. Comparisons between the two or more groups were performed using the Student's *t*-test and ANOVA for normal variables or the Mann–Whitney *U* test and the Kruskal–Wallis test for non-normal variables. R software (version 3.4.2) and GraphPad Prism software (version 8.00) were used for statistical analysis. Biological replicates (individual mice) are shown as individual data points superimposed on bar charts. Significance was conventionally accepted at *p* < 0.05.

## RESULTS

### Global m<sup>6</sup>A Level Was Upregulated in SUN-Injured hiPSC-CMs

The treatment dose and duration of SUN were determined based on preliminary experiments. Our preliminary results showed that the IC<sub>50</sub> of SUN treatment for 24 h

(cell viability serving as the readout) is around 6  $\mu$ M (Supplementary Figure S1A); thus, the subsequent experiments were carried out with 6  $\mu$ M SUN treatment for 24 h and equal volume of DMSO treatment for 24 h served as the control group. Furthermore, we also explored the time kinetics of 6  $\mu$ M SUN in hiPSC-CMs; these results were given in Supplementary Figure S1B.

Figure 1A shows the optical microscope morphology of hiPSC-CMs treated with 6  $\mu$ M of SUN for 24 h. The cell surface area decreased, accompanied by a significant elevation in LDH release and a significant reduction in cell viability in SUN-treated hiPSC-CMs. Furthermore, the immunofluorescence results suggested that the global m<sup>6</sup>A levels in the SUN group increased and that the structure of myocardial sarcomeres became disorganized (Figure 1B). The m<sup>6</sup>A dot blot validated that the global m<sup>6</sup>A level was indeed elevated in the SUN group (Figure 1C). In addition, the colorimetric kit method also verified the upregulation of the global m<sup>6</sup>A level (Figure 1D). Linear regression was used to analyze the relationship between the mRNA m<sup>6</sup>A level and LDH release of hiPSC-CMs after SUN treatment and it was found that a positive correlation was identified between the global m<sup>6</sup>A level and LDH release ( $r = 0.6096$ ,  $p < 0.01$ ) and the global m<sup>6</sup>A level and LDH release gradually increased as the treatment time was prolonged (Figure 1E). Overall, these results

indicated that the dysregulated m<sup>6</sup>A modification in SUN-injured hiPSC-CMs may play important roles in TKI-induced cardiotoxicity.

## Overview of the m<sup>6</sup>A Methylation Map in SUN-Injured hiPSC-CMs

Next, to further decipher the role of elevated m<sup>6</sup>A in SUN-injured hiPSC-CMs, three biological copies of hiPSC-CMs from either the normal control (NC) group or the SUN group were sent for MeRIP-seq and m<sup>6</sup>A MeRIP enrichment regions (peaks) were analyzed after sample normalization (Figure 2A). The m<sup>6</sup>A modification mostly occurred in mRNAs (Figure 2B). A total of 16,399 m<sup>6</sup>A peaks from 4,499 coding gene transcripts (mRNAs) were identified in the NC group. In the SUN group, there were 16,732 m<sup>6</sup>A peaks within 4,427 mRNAs (Figure 2C). To reveal the preferential distribution of m<sup>6</sup>A in transcripts, the metagene profiles of all the identified m<sup>6</sup>A peaks in the entire transcriptome were probed. The results show that the m<sup>6</sup>A peak is preferentially enriched in two sets of coding DNA sequences (CDSs) and the 3'-untranslated region (UTR) (Figures 2D,E). To learn whether a consensus motif existed in the identified m<sup>6</sup>A peaks, we used HOMER software to map the m<sup>6</sup>A methylation. The results showed that m<sup>6</sup>A mainly exists in the consensus sequence of 5'-RRAH-3' and 5'-RRAH-3' (R = A or G; H = A, C, or U) (14). Among the identified m<sup>6</sup>A peaks, the top five conserved

motifs are shown in **Figure 2F**, which was consistent with the well-known “RRACH” consensus motif of m<sup>6</sup>A modification.

### Conjoint Analysis of the MeRIP-seq and RNA-seq Data in SUN-Injured hiPSC-CMs

To further clarify the changes in m<sup>6</sup>A methylation associated with TKI-induced cardiotoxicity, we performed a conjoint analysis of the MeRIP-seq and RNA-seq data. As shown in **Figure 3A**, 20,072 m<sup>6</sup>A peaks (representing 9,892 genes) were identified and there were 2,614 differentially methylated peaks (representing 2,066 genes), among which 919 differentially methylated peaks had hypermethylation and 1,695 differentially methylated peaks had hypomethylation at the log fold change cutoff of ( $\pm 1$ ) and FDR cutoff of  $<0.05$ . The top 10 hypermethylated genes and the top 10 hypomethylated genes are shown in **Table 1**. The analysis of the differentially methylated peak (DMPeaks) distribution at different chromosome loci revealed that the chromosomes with the most m<sup>6</sup>A methylation were chromosome 1 with 308 m<sup>6</sup>A methylation peaks, chromosome 2 with 170 m<sup>6</sup>A methylation peaks, and chromosome 17 with 164 m<sup>6</sup>A methylation peaks (**Figure 3B**). In parallel, RNA-seq was used to determine the transcriptome profile of altered genes. We identified 1,906 differentially expressed genes (DEGs) between the NC and SUN groups, including 990 upregulated DEGs and 916 downregulated DEGs (fold changes 2,  $p < 0.05$ ;

**Figures 3C,D**). The top 10 upregulated mRNAs and the top 10 downregulated mRNAs are shown in **Table 2**. Furthermore, among the 20,072 m<sup>6</sup>A peaks (representing 9,892 genes) identified, there were 2,614 differentially methylated peaks (representing 2,066 genes), 919 hypermethylated peaks, and 1,695 hypomethylated peaks. Accordingly, we identified 244 mRNAs with significant changes in their m<sup>6</sup>A peaks and levels and they could be divided into four quadrants: both the mRNA expression and m<sup>6</sup>A peaks were upregulated (55), mRNA and m<sup>6</sup>A peaks were both downregulated (74), m<sup>6</sup>A peaks were upregulated and mRNA peaks were downregulated (37), and m<sup>6</sup>A peaks were downregulated and mRNA peaks were upregulated (78) (**Figure 3E**). We have validated the transcriptomic study by examining the gene expression level of top 5 upregulated and top 5 downregulated protein coding genes among the 244 intersection genes by RT-qPCR assay. The RT-qPCR results were mostly consistent with RNA-seq (**Supplementary Figure S2**), which might be helpful to solidify our sequencing result. The list of 244 DEGs with significant differential m<sup>6</sup>A peaks is given in **Supplementary Table S2**. Their GO term for enrichment analysis is given in **Supplementary Figure S3**. The GO analysis showed that the biological functions of the 244 mRNAs were mainly enriched in mitogen-activated protein kinase (MAPK) and p53 signaling pathway, while the KEGG analysis repetitiously pointed to apoptotic signaling pathways.

## The GO and the KEGG Enrichment Analyses Revealed the Biological Information Underlying DEGs and Differentially Methylated Genes (DMGs)

To explore the physiological and pathological significance of the DEGs and DMGs, the GO and the KEGG pathway analyses were performed on the key genes identified. The GO analysis showed that the biological functions of upregulated DEGs were mainly enriched in the regulation of angiogenesis and apoptosis signaling pathways (Figure 4A). The downregulated DEGs were mainly involved in microtubule cytoskeleton organization, endomembrane system organization, protein tetramerization, and protein heterodimerization (Figure 4B). Through the KEGG analysis, the upregulated DEGs were mainly enriched in pathways in cell adhesion molecules (CAMs), extracellular matrix (ECM)-receptor interaction, and ribosome biogenesis in eukaryotes (Figure 4C). The downregulated DEGs were mainly involved in cancer pathways, the MAPK signaling pathway, cytokine-cytokine receptor interactions, and the p53 signaling pathway (Figure 4D). In addition, we also performed enrichment analyses on DMGs. These genes were mainly enriched in pathways such as nuclear transport, nucleocytoplasmic transport,

regulation of cell cycle phase transition, and histone modification (Figure 4E). The KEGG analyses showed that these DMGs were related to pathways in cancer, focal adhesion, regulation of actin cytoskeleton, and protein processing in the endoplasmic reticulum (Figure 4F).

## Expression of FTO Was Downregulated, While the Expressions of MELLT14 and ALKBH5 Were Upregulated in SUN-Treated hiPSC-CMs

To further explore whether the m<sup>6</sup>A modification enzyme was involved in SUN-induced hiPSC-CM injury, we examined the expression levels of major methyltransferases and demethylases. Compared with the NC group, the mRNA expression levels of the methylases WTAP and METTL14 in the SUN group were significantly upregulated ( $p < 0.05$ ), whereas the mRNA expression level of FTO (demethylase) was significantly downregulated in the SUN group ( $p < 0.01$ ) (Figure 5A). The downregulation of FTO was again verified in the SUN group by immunofluorescence (IF) staining (Figure 5B). However, the expression of the other two enzymes, METTL3 and ALKBH5, was not altered in SUN-treated hiPSC-CMs. Consistent with the

mRNA expression data, the protein levels of WTAP, METTL14, and FTO exhibited similar trends in SUN-treated hiPSC-CMs (Figure 5C). Collectively, these results indicated that the downregulated FTO as well as the upregulated METTL14 and WTAP might account for the increased global m<sup>6</sup>A level in SUN-injured hiPSC-CMs.

## FTO Downregulation Aggravated SUN-Induced hiPSC-CM Injury

Next, we employed FB23-2, a potent and selective FTO inhibitor that directly binds to FTO and selectively inhibits FTOs m<sup>6</sup>A demethylase activity to examine the role of FTO in SUN-induced hiPSC-CM injury. For FB23-2 treatment, 20  $\mu$ M FB23-2 was added simultaneously with SUN for 24 h. The concentration of FB23-2 was chosen based on a previous report (20). We examined the effect of FB23-2 on global m<sup>6</sup>A level by m<sup>6</sup>A dot blot. The results verified a  $\sim$ 1.7-fold upregulation of global m<sup>6</sup>A level. Cell death was evaluated by PI staining after 24 h of treatment. Interestingly, SUN-induced hiPSC-CM death was exacerbated in the FB23-2 + SUN group (Figures 6A,B). This effect was not observed in normal hiPSC-CMs, indicating that FB23-2 alone would not affect the cell viability of hiPSC-CMs. Furthermore, SUN-induced hiPSC-CM atrophy was also aggravated in the FB23-2 + SUN group, as evidenced by a smaller cell surface area (Figures 6A,C). The colorimetric test kit for LDH release again validated the findings obtained from the PI

staining (Figure 6D). In addition, we knocked down FTO using a FTO shRNA lentiviral particles. The silencing efficiency and inhibited FTO activity as revealed by elevated global m<sup>6</sup>A level were confirmed (Supplementary Figures S6A,B). We observed that FTO shRNA phenocopied the effects of FTO inhibitor in terms of elevating PI-positive cell death, LDH release, and reducing cell surface area (Figures 6A–D). Taken together, these results indicate that FTO plays a protective role in SUN-induced hiPSC-CM injury.

To further explore the role of FTO in SUN-induced cardiotoxicity, we employed a lentivirus construct to overexpress FTO. After verifying the FTO mRNA and global m<sup>6</sup>A level, we transfected hiPSC-CMs with the FTO lentivirus construct or empty vector. The results showed that FTO overexpression by lentivirus construct successfully induced a  $\sim$ 2-fold upregulation of FTO expression and a  $\sim$ 40% downregulation of global m<sup>6</sup>A level (Supplementary Figures S5A,B). Furthermore, FTO overexpression significantly reduced LDH release and improved cell viability in SUN-challenged hiPSC-CMs (Supplementary Figures S5C,D).

To justify that SUN-altered m<sup>6</sup>A effects are cardiomyocytes specific or not, we treated CMECs and CFs with 60 nM or 10  $\mu$ M SUN for 18 h, respectively, referring to the concentration and duration reported in previous studies (23, 24). We then measured the global m<sup>6</sup>A level of mRNA and the transcripts levels of FTO mRNA. Interestingly enough, both the CMECs and

**FIGURE 5 |** Changes in m<sup>6</sup>A methyltransferase and demethylase expression levels in hiPSC-CMs treated with SUN. **(A)** Reverse transcription PCR (RT-PCR) of METTL3, ALKBH5, fat mass and obesity-associated protein (FTO), METTL14, and WTAP; the NC group (*n* = 5) and the SUN group (*n* = 5). **(B)** The levels of FTO expression in the NC and SUN groups as detected by immunofluorescence. Red denotes  $\alpha$ -actinin, green denotes FTO, and blue denotes DAPI. **(C)** The protein expression levels of methyltransferase and demethylase as detected by Western blot (*n* = 5). NS, non-significant, “\*” indicates *p* < 0.05 and “\*\*” indicates *p* < 0.01.

CFs failed to show significant changes in these two parameters in response to SUN (**Supplementary Figures S7A,B,D,E**). Furthermore, cotreatment of FTO inhibitor FB23-2 did not alter the reduced cell viability in response to SUN as revealed by CCK-8 assay (**Supplementary Figures S7C,F**). These results might indicate that the reported effects are cardiomyocytes specific.

## DISCUSSION

In this study, we performed a genome-wide analysis of m<sup>6</sup>A mRNA methylation by MeRIP-seq and RNA-seq in a human stem cell-derived cardiomyocyte model of TKI-induced cardiotoxicity. Our major findings include the following: (a) the global m<sup>6</sup>A level was upregulated in SUN-injured hiPSC-CMs; (b) downregulated FTO as well as upregulated METTL14 and WTAP might account for the increased global m<sup>6</sup>A level in SUN-injured hiPSC-CMs; (c) m<sup>6</sup>A modification was associated with the occurrence and course of TKI-induced cardiotoxicity to some extent; and (d) protected against SUN-induced hiPSC-CM injury. Nevertheless, the specific mechanism of m<sup>6</sup>A methylation in TKI-induced cardiotoxicity remains to be further studied in the future.

Recent studies have shown that m<sup>6</sup>A is involved in the occurrence and development of cancers and cardiac

dysfunction. RNA methyltransferases, demethylases, and m<sup>6</sup>A-binding proteins are frequently altered in human cancer tissues from various organ sources, influencing cancer transcription and oncoprotein expression, cancer cell proliferation, survival, tumor initiation, progression, and metastasis (25, 26). However, there is no consensus on whether altered m<sup>6</sup>A is oncogenic or tumor suppressive. In comparison, studies have reported that m<sup>6</sup>A methylation and FTO have decreased expressions in various pathologic conditions including heart failure and endotoxemia- and hypoxia/reoxygenation-induced cardiac cell injuries (7, 14, 15). In accordance with our present finding, most studies suggest that elevated m<sup>6</sup>A level that result from elevated methylases or reduced demethylases is a deleterious factor for the onset and progression of various cardiovascular diseases (27).

Recently, m<sup>6</sup>A methylation was revealed to play important roles in various cardiovascular diseases, but its role in TKI-induced cardiotoxicity has rarely been studied. In this study, we found that the cell viability of hiPSC-CMs treated with SUN decreased, whereas the release of LDH increased, which suggested that SUN had a damaging effect on hiPSC-CMs. IF staining showed that the m<sup>6</sup>A levels of the SUN group were elevated and the m<sup>6</sup>A dot blot also verified this elevation. Moreover, we also found that the global m<sup>6</sup>A methylation level in SUN-treated hiPSC-CMs was positively correlated with LDH release. Therefore, we employed MeRIP-seq and RNA-seq to

study the transcriptome and methylome in SUN-treated hiPSC-CMs. Through further joint analysis of MeRIP-seq and RNA-seq data, we found significant differences between the m<sup>6</sup>A methylation and mRNA expression levels of 244 genes. We surmised that these potential genes, through m<sup>6</sup>A methylation, are potentially involved in the occurrence and development of TKI-induced cardiotoxicity.

We further conducted the GO and the KEGG analyses of differentially expressed m<sup>6</sup>A methylated genes. Biological processes and pathways indicated apoptotic signaling pathways that were repetitiously enriched by upregulated DEGs. This enrichment pattern coincides with previous SUN cardiotoxicity studies. For instance, a previous study in isolated cardiomyocytes and mice scrutinized the potential mechanisms of SUN-associated cardiac effects. This study concluded that mitochondrial injury and cardiomyocyte apoptosis accounted for SUN-associated cardiotoxicity (28). In a more recent report, apoptotic cell death resulting from mitochondrial damage with reactive oxygen species (ROS) accumulation was shown to be the important contributing mechanism of cardiotoxicity associated with SUN (29). Conversely, thioester and acetyl-CoA metabolic pathways were significantly enriched by downregulated DEGs. Thioesters play a prominent role in metabolism. The central metabolite acetyl-CoA is a thioester that is produced mainly by oxidative decarboxylation of pyruvate or by fatty acid degradation. It is, thus, possible that SUN-induced cardiotoxicity can be ascribed to interrupted mitochondrial energy production.

Interestingly, SUN was previously reported to induce loss of mitochondrial membrane potential and energy rundown in cardiomyocytes (30). Thus, this study further supports the notion that apoptosis induction and energy reduction are the crucial mechanisms of SUN-associated cardiotoxicity.

Fat mass and obesity-associated protein is the first demethylase discovered to be involved in m<sup>6</sup>A modification. Recent high-quality studies have confirmed that FTO plays fundamental roles in many cardiac physiological and pathological processes. Increased m<sup>6</sup>A in RNA was associated with decreased FTO mRNA and protein expression in human and mouse failing hearts. Moreover, adeno-associated virus 9 (AAV9)-mediated myocardial FTO overexpression restores cardiac function in mouse models of myocardial infarction, whereas cardiomyocyte-restricted knockout of FTO mice deteriorates cardiac function (27). Further mechanistic studies revealed that FTO overexpression selectively demethylates cardiac contractile transcripts, thus blocking their degradation and improving their stability and expression under ischemia, which eventually contributed to reduced fibrosis and enhanced angiogenesis (7). Another study found that FTO alleviated cardiac dysfunction by regulating glucose uptake and glycolysis in mice with pressure overload-induced heart failure, the effects of which were associated with demethylation of the glycolysis-related gene *Pgam2* (31). In addition, a similar study reported that FTO cardiomyocyte-specific knockout worsened cardiac dysfunction through transcription-independent mechanisms

of translation regulation (32). All these reports support a cardioprotective role of FTO in different cardiac pathologies. In this study, we detected the major methylases and demethylases in SUN-treated hiPSC-CMs and found that FTO was significantly downregulated. To verify the role of FTO in SUN-induced cardiotoxicity, we treated hiPSC-CMs with FB23-2, a potent and selective FTO inhibitor and demonstrated that FB23-2 can aggravate the cell injury elicited by SUN, cause damage to the sarcomeres of cardiomyocytes, and deteriorate cell atrophy. Together with previous findings, this study might add a conceptual framework for targeting FTO as a therapeutic for various cardiovascular diseases. Notably, this study also found that the expression levels of METTL14 and WTAP increased in SUN-treated hiPSC-CMs and their functional roles remain to be further clarified.

This study failed to reveal the downstream regulatory mechanisms by which SUN-stimulated m<sup>6</sup>A upregulation regulates the mRNA expression of related genes, which warrants further investigations. Nonetheless, we have depicted the m<sup>6</sup>A modification landscape of SUN-treated hiPSC-CMs with transcriptome-wide unbiased epitranscriptomics and revealed a potential role of m<sup>6</sup>A and m<sup>6</sup>A eraser FTO in SUN-induced cardiotoxicity, which would lay a solid foundation for further detailed mechanistic studies.

## CONCLUSION

This study provides the first overview of the m<sup>6</sup>A methylation map in SUN-injured hiPSC-CMs to decipher the RNA post-transcriptional epigenetic mechanisms of TKI-induced cardiotoxicity. Through MeRIP-seq, we found that the m<sup>6</sup>A methylation level in 2,614 mRNAs changed significantly. Combined analysis of the m<sup>6</sup>A peak and mRNA expression showed that 244 mRNAs were significantly changed after SUN treatment. These genes with varying levels of m<sup>6</sup>A modification may play an important role in the process of TKI-induced cardiotoxicity. In addition, we found that inhibiting FTO can aggravate the myocardial toxicity caused by SUN, which suggests a novel therapeutic target for TKI-induced cardiotoxicity.

Hypertension is the most significant risk factor for heart failure in doxorubicin (DOX)-treated childhood cancer survivors. We previously developed a two-hit mouse model of juvenile DOX-induced latent cardiotoxicity that is exacerbated by adult-onset angiotensin II (ANGII)-induced hypertension. It is still not known how juvenile DOX-induced latent cardiotoxicity would predispose the heart to pathologic stimuli that do not cause hypertension. Our main objective is to determine the cardiac effects of ANGI (a hypertensive pathologic stimulus) and isoproterenol (ISO, a non-hypertensive pathologic stimulus) in adult mice pre-exposed to DOX as juveniles. Five-week-old male C57BL/6N mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and then allowed to recover for 5 weeks. Thereafter, mice were administered either ANGI (1.4 mg/kg/day) or ISO (10 mg/kg/day) for 14 days. Juvenile exposure to DOX abrogated the hypertrophic response to both ANGI and ISO, while it failed to correct ANGI- and ISO-induced upregulation in the hypertrophic markers, ANP and BNP. ANGI, but not ISO, worsened cardiac function and exacerbated cardiac fibrosis in DOX-exposed mice as measured by echocardiography and histopathology, respectively. The adverse cardiac remodeling in the DOX/ANGI group was associated with a marked upregulation in several inflammatory and fibrotic markers and altered expression of Ace, a critical enzyme in the RAAS. In conclusion, juvenile exposure to DOX causes latent cardiotoxicity that predisposes the heart to a hypertensive pathologic stimulus (ANGI) more than a non-hypertensive stimulus (ISO), mirroring the clinical scenario of worse cardiovascular outcome in hypertensive childhood cancer survivors.

## INTRODUCTION

The survival rate of childhood cancer has increased from 60% to more than 85%, thanks to advanced diagnosis, treatment, and care models (1). Indeed, there are more than 500,000 childhood cancer survivors in the United States and this number is expected to increase. Although the increased survivorship is a cause for celebration, up to 73% of childhood cancer survivors suffer from long-term health complications (2). Cardiovascular disease is one of the most common long-term complications in survivors and the second leading cause of death in childhood cancer survivors after secondary malignancy (2). The high burden of cardiovascular diseases in childhood cancer survivors is mainly attributed to cardiotoxic cancer treatments such as anthracyclines and radiation therapy (3). Doxorubicin (DOX) is an anthracycline chemotherapeutic agent widely used in the treatment of lymphoma, leukemia, and other pediatric cancers, despite its known cardiotoxic effects (4). Since the severe cardiotoxic effects of DOX are dependent on the cumulative dose, the current treatment protocols usually do not exceed this threshold. Therefore, the rates of severe cardiovascular complications have declined in recent years. However, it has also been shown that low cumulative doses of DOX cause subclinical cardiotoxicity in childhood cancer survivors (5–7).

DOX-induced subclinical cardiotoxicity predisposes the survivors to adult-onset cardiovascular risk factors in a two-hit manner (8, 9). Given the expected long survivorship life in childhood cancer survivors, many of them would develop multiple cardiovascular risk factors later in their adult life, which can be considered as “second hits.” Since hypertension is the most significant cardiovascular risk factor for all adverse cardiac events, including heart failure and cardiac death, in anthracycline-treated childhood cancer survivors (10), we have recently developed a two-hit mouse model of juvenile DOX-induced latent cardiotoxicity that is exacerbated by adult-onset angiotensin II (ANGII)-induced hypertension (11). Nevertheless, it is still not known how juvenile DOX-induced latent cardiotoxicity would predispose the heart to other cardiovascular pathologic stimuli that do not cause hypertension. In the current study, we characterize the detrimental synergy in the DOX/ANGII model in parallel to a new model wherein juvenile DOX exposure is followed by adult-onset catecholamine stress by daily injections of isoproterenol (ISO). ISO is a non-specific beta-adrenoceptor agonist that is commonly used to induce a dose-dependent cardiac pathology without elevating blood pressure (12–15). Characterizing both DOX/ANGII and DOX/ISO models is critical to understanding why hypertension is the most significant risk factor for cardiovascular morbidity and mortality in anthracycline-treated childhood cancer survivors and thereby devising effective therapeutic strategies against this significant clinical problem.

## MATERIALS AND METHODS

### Animals

Animal procedures were approved by the Institutional Animal Care and Use Committee (IACUC) at the University of Minnesota (Protocol ID: 1807-36187A). Animal housing and all animal procedures were performed at the University of Minnesota according to the approved protocol. Male 4-week old C57BL/6N mice were purchased from Charles River Laboratories. All mice were housed in groups of 3–4 mice per cage, maintained under standard specific pathogen free (SPF) conditions, and given food and water *ad libitum* in a 14h light/10h dark cycle and at  $21 \pm 2^\circ\text{C}$ . After a 1-week acclimation period, 5-week old mice were administered either DOX (4 mg/kg/week for 3 weeks, DOX group) or equivalent volume of sterile normal saline (control group). The mice were monitored twice per week and were weighed once weekly. Five-weeks following the last DOX injection at the age of 12 weeks (the age of young adult mice), control and DOX-treated mice were assigned to either the ANGIO or ISO experiments. In the ANGIO experiment (Figure 1A), control and DOX-exposed mice were infused with ANGIO (1.4 mg/kg/day) or sterile normal saline for 14 days through subcutaneously implanted ALZET osmotic mini-pumps (Durect Corp, Cupertino, CA) to induce hypertension as previously reported (11, 16, 17). Animals were anesthetized with isoflurane (2–3%) and surgical site was clipped then cleaned with betadine and alcohol. Anesthetic level was assessed by toe pinch and respiratory rate. A skin incision was made with surgical scissors in the mid-scapular area, a filled pump was inserted into the pocket, and the wound was closed with skin staples. For analgesia, animals were administered carprofen (5 mg/kg) just prior to the surgery and daily for 3 days following surgery and monitored for any signs of infection or suture opening. In the ISO experiment (Figure 1E), 10 mg/kg ISO or an equivalent volume of sterile normal saline was administered by subcutaneous daily injection for 14 days as previously reported (12). At the end of the experiment, mice were humanely euthanized by decapitation under isoflurane anesthesia and hearts were harvested.

### Echocardiography

All heart function and wall thickness data was measured using echocardiography. Baseline cardiac function was assessed 5 weeks after the last DOX treatment on the day prior to the start of the 14 day ANGIO or ISO challenge. To determine the response to prolonged ANGIO administration, cardiac function was assessed by echocardiography on the 15th day after implanting the mini-osmotic pumps containing either saline or ANGIO in control and DOX-treated mice ( $n = 6-9$  per group). To determine the response to ISO administration, cardiac function was assessed by echocardiography 24h following the last dose of ISO or sterile saline injections in control and DOX-treated mice ( $n = 6$  per group). Echocardiography was performed using the Vevo 2100 system (VisualSonics, Inc., Toronto, Ontario, Canada) equipped with an MS400 transducer. Anesthesia was induced with 3% isoflurane in oxygen and maintained at 1–2% during the procedure. Mice were secured in a supine position on a heated

physiologic monitoring stage. Parasternal short axis images of the left ventricle were obtained in M-Mode at the level of the papillary muscles. Endocardial and epicardial borders were manually traced over three cardiac cycles and measures of cardiac function and morphometry were calculated using VisualSonics cardiac measurement package of the Vevo 2100.

## Histopathology

Left ventricular (LV) heart sections were collected, fixed in 10% neutral buffered formalin and embedded in paraffin. Four-micron sections were stained with hematoxylin and eosin (H&E) or Masson's trichrome stain. Histopathologic evaluation was performed by a board-certified veterinary pathologist who was blinded to the experimental group. Inflammation and fibrosis were assessed as follows: 0, absent; 1, minimal inflammation or fibrosis; 2, mild inflammation or fibrosis; 3, moderate inflammation or fibrosis; and 4, marked inflammation or fibrosis. Sections from each heart were also immunohistochemically stained for expression of MAC-2 (galectin-3). In brief, four-micron sections were dewaxed and rehydrated prior to antigen retrieval. Thereafter, sections were incubated with anti-galectin-3 antibody (clone M3/38, Cedarlane Labs, Burlington, NC) according to manufacturer's instruction. The number of MAC-2 positive cells was manually quantified on the five most cellular 200X images. To measure cardiomyocyte cross-sectional surface area from histological sections, we stained dewaxed and rehydrated sections with Fluorescein isothiocyanate-conjugated wheat germ agglutinin (5 µg/ml, Vector Laboratories FL-1021) and 4',6-diamidino-2-phenylindole (DAPI, Invitrogen D3571). Stained slides were mounted with Vectashield (Vector Laboratories H-1000). Images were acquired using a Nikon TiE or a Zeiss Axio Images M1 microscope, both equipped with a digital black/white camera. Wheat germ agglutinin binds to glycosylated proteins, which are enriched in the membranes of cells. Based on the difference in size between cardiomyocytes and non-cardiomyocytes, we traced the area of cardiomyocytes using Image J. We selected areas where cardiomyocytes had a round shape, indicative of a cross-sectioned cardiomyocytes. We traced at least 100 cardiomyocytes per heart in different areas of a cross-sectioned heart. Images were quantified by a researcher blinded to the treatment.

## RNA Extraction and Real-Time PCR

Total RNA was extracted from 20 mg frozen heart tissue using 300 µl Trizol reagent (Life Technologies, Carlsbad, CA) according to manufacturer's instructions. RNA concentrations were measured at 260 nm using a NanoDrop 8000 spectrophotometer (Thermo Fisher Scientific, Wilmington, DE) and first-strand cDNA was synthesized from 1.5 µg total RNA using the high-capacity cDNA reverse transcription kit (Applied Biosystems, Foster City, CA) according to manufacturer's instructions. Specific mRNA expression was quantified by real-time PCR using SYBR Green (Applied Biosystems) and performed on an ABI 7900HT instrument (Applied Biosystems). Thermocycler conditions were as follows: 95°C for 10 min, followed by 40 PCR cycles of denaturation at 95°C for 15 s, and annealing/extension at 60°C for 1 min. Gene expression

was determined using previously published primers for atrial natriuretic peptide (ANP), b-type natriuretic peptide (BNP), Cyclooxygenase-2 (*Cox2*), Collagen 1a1 (*Col1a1*), Collagen 3a1 (*Col3a1*), Galectin-3 (*Lgals3*), Angiotensin converting enzyme (*Ace*), ANGII type 1 receptor-*a* (*Agtr1a*), and ANGII type 1 receptor-*b* (*Agtr1b*). Primer sequences are listed in **Supplementary Table 1**. The mRNA expression levels were normalized to beta-actin and are expressed relative to the control group. Relative gene expression was determined by the  $\Delta\Delta CT$  method. Primer specificity and purity of the final PCR product were confirmed by melting curve analysis.

## Statistical Analysis

Data were analyzed using GraphPad Prism software (version 9.0, La Jolla, CA) and are presented as individual data points and their means  $\pm$  standard errors of the mean (SEM). Comparisons among different treatment groups were performed by ordinary two-way analysis of variance (ANOVA), followed by Tukey's multiple comparison *post-hoc* analysis. Comparisons between two groups were performed by unpaired student's two-tailed *t*-test. Statistical analyses for histopathologic grading were performed using the non-parametric Kruskal-Wallis test. A *p*-value of  $<0.05$  was taken to indicate statistical significance.

## RESULTS

### Juvenile Exposure to DOX Abrogated the Hypertrophic Response to Both ANGII and ISO

Juvenile exposure to DOX (4 mg/kg/week for 3 weeks) did not cause significant morbidity or mortality in mice, similar to our earlier study (11). In addition, treatments with either ANGII or ISO were not associated with significant morbidity or mortality, when administered to control or DOX-treated mice (**Supplementary Figure 1**).

Corroborating previous studies (16, 18), 2 weeks of ANGII infusion or ISO injections caused cardiac hypertrophy in control mice as demonstrated by an increase in the heart weight to tibia length (HW/TL) (**Figures 1B,F**). Remarkably, juvenile exposure to DOX prevented both ANGII- and ISO-induced cardiac hypertrophy as evident by a reduction in HW/TL (**Figures 1B,F**). To follow on this result, we measured cardiomyocyte surface area to determine if the reduction of heart weight is due to cardiomyocyte atrophy (**Figures 1C,D,G,H**). Mice exposed to DOX/ANGII had the smallest surface area among the groups and this group was significantly different from mice treated with ANGII only (**Figures 1C,D**). No statistically significant differences in cardiomyocyte surface area were observed in mice treated with ISO (**Figures 1G,H**). Images shown are representative images for each group, where wheat germ agglutinin staining is pseudo-colored green (**Figures 1C,G**).

Measurements of ANP and BNP mRNA expressions were assessed to determine the cardiotoxicity that was induced on the heart by the pharmacological interventions. There were no differences observed in ANP and BNP mRNA expression between control and ANGII treated mice. The combination

of DOX/ANGII significantly increased the expression of these markers compared to DOX alone (Figures 2A,B). On the other hand, it appears that DOX did not exacerbate the ISO mediated increases in ANP and BNP since no statistically significant differences were observed between DOX/ISO and ISO alone (Figures 2C,D).

### ANGII but Not ISO Worsens Cardiac Function in DOX-Exposed Mice

There were no significant changes in systolic cardiac function 5 weeks after the last DOX treatment, as evidenced by no significant difference in ejection fraction or fractional shortening (Table 1). Cardiac output and stroke volume were significantly lower in DOX-exposed mice than that in saline-treated mice, which was associated with a reduction in LV mass and wall thickness (Table 1). Neither DOX nor ANGII alone was sufficient to significantly reduce the cardiac function in mice (Figures 3A–D); however, juvenile exposure to DOX followed by adult-onset ANGII-induced hypertension caused a significant deterioration in cardiac function parameters as shown by a decrease in cardiac output (Figure 3B), stroke volume (Figure 3C), and ejection fraction (Figure 3D). Intriguingly, when DOX-exposed mice were subjected to ISO as a second cardiovascular hit, the cardiac function of DOX/ISO-treated mice

did not significantly differ from the other groups (Figures 3E–H). Tables 2, 3 show detailed echocardiography measurements after 14 days of ANGII, ISO, or saline treatment in control and DOX-treated mice.

### ANGII but Not ISO Worsens Cardiac Fibrosis in DOX-Exposed Mice

Histopathology analysis using H&E and Masson's trichrome stains revealed marked inflammatory cell infiltration and cardiac fibrosis in the DOX/ANGII group as compared to the control (Figures 4A–C). Although a few mice in the DOX and ANGII groups showed signs of cardiac fibrosis at varying degrees, neither DOX nor ANGII alone was sufficient to cause a statistically significant effect on cardiac fibrosis (Figure 4C). The combination of DOX and ANGII significantly increased fibrosis suggesting that DOX potentiates the fibrosis inducing action of ANGII. On the other hand, ISO treatment caused modest, but statistically significant, cardiac fibrosis which was not exacerbated by DOX treatment (Figures 4D–F). To ascertain the molecular determinants of the observed fibrotic changes, we measured gene expression of several inflammatory and fibrotic markers. ANGII caused a significant induction of the inflammatory marker *Cox-2* (Figure 5A) and the fibrotic markers, *Col1a1* and *Col3a1* (Figures 5B,C). Juvenile exposure

to DOX mildly but not significantly exacerbated ANGII-induced upregulation of inflammatory and fibrotic markers (Figures 5A–C). Marked increases in inflammatory and fibrotic markers were observed in DOX/ANGII treated mice compared to mice only treated with DOX. On the other hand, DOX/ISO had no exacerbating effect on *Cox-2* or *Col3a1* expression (Figures 5D,F), while there was a significant reduction in *Col1a1* expression in the DOX/ISO treated mice compared to ISO alone (Figure 5E).

Since macrophage infiltration plays an important role in cardiac fibrosis, we measured the expression the fibrotic marker galectin-3 by measuring MAC-2 positive cells by immunohistochemistry as well as the gene expression of galectin-3 (*Lgals-3*). As expected, ANGII caused a significant increase in the number of MAC-2 positive cells (Figures 6A,B) but not a significant induction of *Lgals-3* gene expression (Figure 6C). In agreement with the exacerbation of cardiac fibrosis in the DOX/ANGII group, DOX/ANGII-treated mice had the highest number of MAC-2 positive cells (Figures 6A,B). Juvenile exposure to DOX significantly aggravated ANGII-induced upregulation of *Lgals-3* gene expression (Figure 6C). ISO caused a modest but significant increase in the number of MAC-2 positive cells (Figures 6D,E) and caused a significant upregulation of *Lgal-3* gene expression (Figure 6F). However, juvenile exposure to DOX did not change the effects of ISO on these parameters (Figures 6D–F).

## Perturbed RAAS Gene Expression in the DOX/ANGII Model

Since DOX has been shown to alter the renin-angiotensin-aldosterone-system (RAAS) in different ways (19), we sought to

determine whether DOX-induced alteration in the RAAS may have played a role in the detrimental synergy between DOX and ANGII. To this end, we determined the effects of DOX, ANGII, and DOX/ANGII on expression of the RAAS genes in the heart. Interestingly, the gene expression of angiotensin converting enzyme (*Ace*) was significantly upregulated in the DOX/ANGII group compared to DOX alone (Figure 7A). Next, measurements of the *Atgr1a* and *Atgr1b*, the gene encoding for the ANGII type 1 receptor (AT1) were measured and no statistically significant differences were observed among the groups (Figures 7B,C).

## DISCUSSION

Childhood cancer survivors have a considerably increased risk for premature cardiovascular diseases (20), with an estimated 15 times higher risk of heart failure than their siblings who did not have cancer (2). Nearly 50% of pediatric cancer patients receive anthracyclines such as doxorubicin (DOX), which are known to cause cardiotoxicity (21). Although the risk of anthracycline-induced cardiotoxicity increases with a higher anthracycline cumulative dose (22), latent (subclinical) cardiotoxicity occurs in children who receive low doses of anthracyclines (5–7). Anthracycline-induced subclinical cardiotoxicity is characterized by reduction in the left ventricular mass, mild cardiac fibrosis, and modest decline in ejection fraction (5–7). This latent cardiotoxicity can be unmasked and overt cardiomyopathy precipitated by other cardiovascular risk factors in adulthood, in a two-hit manner (10). We designed the current experimental protocol to mimic the scenario in cancer survivors that undergo DOX treatment at young age. With this protocol, we are able to show that latent cardiotoxicity caused by juvenile exposure to DOX is exacerbated when adult mice undergo a hypertensive “second-hit” on the heart. We used ANGII and ISO as two pharmacological agents that both increase the stress on the heart through distinct mechanisms. In this report, we show that the combination of DOX and ANGII causes the most changes to heart size, cardiac function and fibrosis. While the combination of DOX and ISO shows modest changes in heart size, cardiac function and fibrosis are not affected (Figure 8).

Most preclinical models of juvenile DOX-induced cardiotoxicity used high cumulative doses of DOX that were enough to cause immediate or delayed cardiac dysfunction (23–26). Although clinically relevant, animal models for juvenile DOX cardiotoxicity have rarely adopted the two-hit models. Huang *et al.* demonstrated that low doses of DOX administered to very young mice, at postnatal day 5, did not cause immediate cardiac dysfunction. DOX-exposed mice developed normally and had no obvious cardiac dysfunction as adults. However, juvenile exposure to DOX exacerbated cardiac pathology in response to an adult-onset pathologic stimulus (myocardial infarction) and even a physiologic stimulus (swimming exercise) (27). Since hypertension is the most significant cardiovascular risk factor for all adverse cardiac events, including heart failure and cardiac death, in anthracycline-treated childhood cancer survivors (10), we have recently developed another two-hit mouse model of juvenile DOX-induced latent cardiotoxicity

**FIGURE 3 |** ANGII, but not ISO, worsens cardiac function in DOX-exposed mice. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to (A–D) ANGII (1.4 mg/kg/day for 14 days) or (E–H) ISO (10 mg/kg/day for 14 days). Cardiac function was determined by trans-thoracic echocardiography ( $n = 5$ –9 per group). (A,E) Representative M-Mode images from parasternal short axis view of the heart. (B,F) Cardiac output. (C,G) Stroke volume. (D,H) Ejection fraction. Values are represented as means  $\pm$  SEM. Statistical significance of pairwise comparisons was determined by two-way ANOVA with Tukey's *post-hoc* analysis ( $*p < 0.05$ ,  $**p < 0.01$ ). that is exacerbated by adult-onset ANGII-induced hypertension (11). Similar to Huang et al., we demonstrated that low doses of DOX (4 mg/kg/week for 3 weeks) did not cause immediate cardiac dysfunction in juvenile mice, but predisposed to late-occurring detrimental cardiovascular changes when the mice were challenged by ANGII-induced hypertension (11). However, unlike Huang et al., our DOX administration regimen starts at 5 weeks of age, equivalent to 10 years in human life. Therefore, these dosage regimens model latent cardiotoxicity in anthracycline-treated pediatric cancer patients who do not immediately develop overt cardiac dysfunction but are left with “weaker” hearts that predispose them to other cardiovascular insults, corroborating the findings of several clinical studies (5, 28–31).

Nevertheless, it is still not known how this low-dose DOX regimen would predispose the heart to other cardiovascular pathologic stimuli that do not cause hypertension. To answer this question, we subjected control and DOX-treated mice to a regimen of ISO injections (10 mg/kg/day for 14 days). ISO is a non-specific beta-adrenoceptor agonist that is commonly used to induce a dose-dependent cardiac pathology without elevating blood pressure (12–15). We have previously demonstrated that this dosage regimen causes cardiac hypertrophy, mild

cardiac dysfunction, and modest cardiac fibrosis in C57BL/6N male mice (12). In the current study, we characterize the DOX/ANGII model in parallel to the DOX/ISO model to better understand why hypertension is the most significant risk factor for cardiovascular morbidity and mortality in anthracycline-treated childhood cancer survivors.

Cardiac atrophy and thinning of the LV ventricular walls are common late effects of anthracycline therapy in childhood cancer survivors (32–35). Intriguingly, a study has shown that reduction in the LV mass is associated with worsening of heart failure symptomatology independent of LV ejection fraction in adult cancer survivors (36), demonstrating the predictive value of LV mass. However, the association between LV mass and heart failure symptomatology has not been determined in childhood cancer survivors. We previously demonstrated that juvenile exposure to DOX prevented the adaptive cardiac hypertrophy in response to ANGII-induced hypertension (11). However, it is not known whether juvenile exposure to DOX would also prevent adaptive cardiac hypertrophy in response to other hypertrophic stimuli. In the current study, juvenile exposure to DOX prevented the adaptive cardiac hypertrophy in response to both ANGII and ISO. Indeed, ANGII and ISO cause cardiac hypertrophy *via* different pathways. ANGII induces cardiac hypertrophy directly

through activating the AT1 receptors on cardiomyocytes and indirectly through elevating the afterload (37). In contrast, ISO activates the beta-adrenoceptors on cardiomyocytes to elicit a direct hypertrophic effect (37). ISO-induced tachycardia may also contribute to its hypertrophic effect indirectly. The ability of DOX to prevent cardiac hypertrophy in response to both pathologic stimuli suggest that DOX interferes with common downstream pathways fundamental to the development of cardiac hypertrophy.

Although high-dose DOX causes cardiac atrophy due to apoptotic and necrotic cell death and loss of cardiomyocytes (38), experimental studies using low/divided-dose DOX have suggested that DOX-induced cardiomyocyte atrophy is the main culprit leading to cardiac atrophy and reduction of LV mass with minimal apoptotic cell death (39, 40). We demonstrate that mice with juvenile exposure to DOX had the smallest cardiomyocyte surface area after ANGII exposure. These experimental observations have recently been supported by a clinical study reporting that the reduction in LV mass after anthracycline therapy is due to cardiomyocyte atrophy in breast cancer patients (41). Another recent preclinical study has shown that acute DOX administration causes dose-dependent cardiac atrophy that parallels the decrease in contractile function (39). In

our current study, we demonstrate that chronic administration of low-dose DOX caused cardiac atrophy without reducing the contractile function of the heart. The contractile function of the heart was only affected when the juvenile exposure of DOX was followed by ANGII-induced hypertension. ANGII cause pathologic cardiac hypertrophy characterized by the induction of fetal gene expression such as *ANP* and *BNP*, adverse cardiac remodeling, and reduction in cardiac function parameters. Therefore, in the current work, we determined the effect of juvenile DOX exposure on these parameters. Although we previously showed that juvenile exposure to DOX induced *ANP* gene expression 1 week after the last DOX injection (11), there is no significant change in *ANP* or *BNP* in DOX-exposed mice 7 weeks after the last DOX injection. Only the combination of DOX/ANGII was able to significantly elevate the markers of pathological hypertrophy. Although juvenile exposure to DOX prevented the hypertrophic growth of the heart in response to ANGII, it did not abrogate the molecular determinants of pathological cardiac hypertrophy induced by these stimuli.

We also determined the effect of juvenile exposure to DOX on cardiac remodeling in response to both ANGII and ISO. In our previous study describing the DOX/ANGII model (11), the effect on cardiac fibrosis had not been determined.

**FIGURE 4 |** ANGII, but not ISO, worsens cardiac fibrosis in DOX-exposed mice. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to (A–C) ANGII (1.4 mg/kg/day for 14 days) or (D–F) ISO (10 mg/kg/day for 14 days). Representative images from H&E (A,D) and Masson's trichrome stained heart sections (B,E). (C,F) Semi-quantification of fibrosis score derived from Masson's trichrome stain ( $n = 5-6$  per group). Statistical significance was determined by non-parametric Kruskal-Wallis test (\* $p < 0.05$ , \*\* $p < 0.01$ ). ANGII, Angiotensin II; DOX, doxorubicin; H&E, hematoxylin and eosin; ISO, isoproterenol.

**FIGURE 5 |** ANGII, but not ISO, exacerbates the upregulation of inflammatory and fibrotic markers in DOX-exposed mice. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to (A–C) ANGII (1.4 mg/kg/day for 14 days) or (D–F) ISO (10 mg/kg/day for 14 days). The mRNA expression of (A,D) the inflammatory marker *Cox-2*, and the fibrotic markers (B,E) *Col1a1* and (C,F) *Col3a1* was determined by real-time PCR ( $n = 5$ –6 per group). Results were normalized to beta-actin and are expressed relative to the control group. Statistical significance of pairwise comparisons was determined by two-way ANOVA with Tukey's *post-hoc* analysis ( $p < 0.05$ ,  $**p < 0.01$ ,  $***p < 0.001$ ,  $****p < 0.0001$ ). ANGII, Angiotensin II; DOX, doxorubicin; ISO, isoproterenol.

**FIGURE 6 |** ANGII, but not ISO, exacerbates the upregulation of MAC-2 in DOX-exposed mice. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to (A–C) ANGII (1.4 mg/kg/day for 14 days) or (D–F) ISO (10 mg/kg/day for 14 days). Representative images from (A,D) MAC-2 stained heart sections. (B,E) Semi-quantification of MAC-2 positive cells ( $n = 5-6$  per group). The mRNA expression of (C,F) *Lgals-3* was determined by real-time PCR ( $n = 5-6$  per group). Results were normalized to beta-actin and are expressed relative to the control group. Statistical significance of pairwise comparisons was determined by two-way ANOVA with Tukey's *post-hoc* analysis (\* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ , \*\*\*\* $p < 0.0001$ ). ANGII, Angiotensin II; DOX, doxorubicin; ISO, isoproterenol; Lgals-3, lectin, galactoside-binding, soluble-3.

**FIGURE 7 |** Perturbation of the RAAS pathway in the DOX/ANGII model. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to ANGII (1.4 mg/kg/day for 14 days). The mRNA expression of **(A)** *Ace*, **(B)** *Agtr1a*, and **(C)** *Agtr1b* was determined by real-time PCR ( $n = 5-6$  per group). Results were normalized to beta-actin and are expressed relative to the control group. Statistical significance of pairwise comparisons was determined by two-way ANOVA with Tukey's *post-hoc* analysis (\*\* $p < 0.01$ ). *Ace*, Angiotensin converting enzyme; *Agtr1a*, Angiotensin II type1 receptor-a; *Agtr1b*, Angiotensin II type1 receptor-b; ANGII, Angiotensin II; DOX, doxorubicin.

**FIGURE 8 |** Divergent cardiac effects of ANGII and ISO in adult mice pre-exposed to DOX as juveniles. Male 5-week old mice were administered DOX (4 mg/kg/week) or saline for 3 weeks and allowed to recover for 5 weeks prior to exposure to ANGII (1.4 mg/kg/day for 14 days) or ISO (10 mg/kg/day for 14 days). Juvenile exposure to DOX prevented both ANGII- and ISO-induced cardiac hypertrophy, but failed to correct the upregulation in hypertrophic markers. ANGII, but not ISO, worsened cardiac function, exacerbated cardiac fibrosis, and upregulated inflammatory and fibrotic markers in DOX-exposed mice. ANGII, Angiotensin II; DOX, doxorubicin; ISO, isoproterenol.

In the current study, we demonstrate that juvenile exposure to DOX did not cause significant cardiac fibrosis in naïve mice, but it exacerbated ANGII-induced cardiac fibrosis. The exacerbated cardiac fibrosis was associated with a marked upregulation in several inflammatory and fibrotic markers in the DOX/ANGII-treated mice. Importantly, MAC-2 positive cells and the expression of *Lgals-3* gene encoding galectin-3 were much higher in hearts of DOX/ANGII-treated mice than in hearts of mice receiving either DOX or ANGII alone. In contrast to cardiac atrophy, which is a consistent feature of anthracycline-induced cardiotoxicity, the prevalence and extent of cardiac fibrosis in anthracycline-treated childhood cancer survivors is controversial. In a cohort of childhood cancer survivors, the prevalence of left ventricular and right ventricular fibrosis was 9 and 38%, respectively; however, these values were not compared to a healthy control group (42). Some studies report anthracycline-treated childhood cancer survivors to show modest myocardial fibrosis as evident by an increased extracellular volume fraction (35). On the other hand, other studies demonstrate the absence of a statistically significant increase in myocardial fibrosis in survivors compared to healthy control subjects (43, 44). Since there is no clinical data reporting the association between myocardial fibrosis and cardiovascular risk factors in anthracycline-treated survivors, it may be possible that the discrepancy in these clinical studies arise from the confounding effect of other cardiovascular diseases, particularly hypertension.

In contrast to the DOX/ANGII model, juvenile exposure to DOX did not exacerbate ISO-induced cardiac fibrosis. Surprisingly, the gene expression of the fibrotic marker collagen 1a1 was lower in DOX/ISO-treated mice as compared to mice treated with ISO alone. DOX-induced cardiotoxicity has been shown to attenuate the acute effects of ISO on the heart including its positive inotropic effect (45), acute decrease of myocardial stiffness (46), and stimulation of adenylyl cyclase (47). Nevertheless, the impact of DOX exposure on the chronic effects of ISO has not been previously reported. ANGII-induced increase in afterload coupled with DOX-induced thinning of the left ventricular walls is expected to markedly increase ventricular wall stress according to the Law of LaPlace. Since ISO does not increase the afterload, its effects on the heart of DOX-exposed mice would be expected to be much milder.

DOX-induced cardiotoxicity has been shown to be more severe in hypertensive experimental animals than in normotensive ones (48–50). An important distinction between these studies and our model is the fact that these studies administered DOX to already hypertensive animals, while in our model DOX is administered to young normotensive mice then challenged by ANGII-induced hypertension in their adult life, 5 weeks after the last DOX injection. In an attempt to determine the mechanism of the detrimental synergy between juvenile exposure to DOX and adult-onset ANGII-induced hypertension, we determined the effect of these experimental conditions on

the renin-angiotensin-aldosterone-system (RAAS) genes. In the current study, juvenile exposure to DOX had no significant effect on the expression of *Ace*, *Agtr1a*, and *Agtr1b* genes. Nevertheless, there was a significant upregulation in *Ace* gene expression in the DOX/ANGII group. Similarly, juvenile exposure to DOX prevented ANGII-induced downregulation of *Agtr1a*, which encodes the AT1 receptor. ANGII mediates its detrimental effects *via* the AT1 receptors, while AT2 receptors mediate cardioprotective effects. DOX has been previously shown to alter the RAAS in different ways (19). DOX has been shown to significantly increase the expression of AT1 receptors and reduce that of AT2 receptors in a rat model of DOX-induced heart failure (51). Although there was no significant change in the mRNA expression of RAAS genes in the hearts of rabbits treated with a single dose of DOX (52), the plasma and myocardial levels of ANGII were increased three-fold in a rat model of DOX-induced heart failure (53). DOX treatment has also been shown to increase myocardial ACE activity in the cardiac tissues of hamsters (54). Intriguingly, angiotensin receptor blockers (ARBs) have been shown to ameliorate anthracycline-induced cardiotoxicity in animal models (55–57). Importantly, a recent meta-analysis shows that RAAS antagonists were the most efficient drugs to prevent anthracycline-induced cardiotoxicity with 84% risk reduction (58).

The current study has some limitations that warrant discussion. First, we have not measured the blood pressure in our experimental groups. We previously reported that juvenile exposure to DOX caused an increase in blood pressure, which was further exacerbated by ANGII infusion (11). ISO is a beta-adrenergic agonist that does not increase blood pressure, as previously reported by several other investigators (14). We also did not measure the plasma levels of natriuretic peptides, ANP and BNP. Although the induction of fetal gene expression as a hallmark of pathologic hypertrophy is usually assessed by measuring the gene expression of ANP and BNP (59, 60), measuring plasma levels of these peptides would have strengthened our conclusions.

In conclusion, this study shows that juvenile exposure to DOX differentially exacerbates ANGII—but not ISO-induced adverse cardiac remodeling. There was a marked detrimental synergy between juvenile exposure to DOX followed by ANGII-induced hypertension, which resulted in cardiac dysfunction and adverse cardiac remodeling. This preclinical mouse model highlights the clinical finding that hypertension is the most significant risk factor for heart failure in anthracycline-treated childhood cancer survivors. Since ANGII may cause cardiac damage through direct mechanism beyond elevating blood pressure, future studies are planned to delineate the mechanisms of these deleterious effects by targeting elements of RAAS system.

Cardiovascular toxicity in cancer patients receiving chemotherapy remains one of the most undesirable side effects, limiting the choice of the most efficient therapeutic regimen, including combinations of different anticancer agents. Anthracyclines (doxorubicin) and antimetabolites (5-fluorouracil (5-FU), capecitabine) are among the most known agents used in breast cancer and other neoplasms and are associated with cardiotoxic effects. Extra-virgin olive oil (EVOO) is rich in polyphenols endowed with antioxidant cardioprotective activities. Olive mill wastewater (OMWW), a waste product generated by EVOO processing, has been reported to be enriched in polyphenols. In this study, we investigated the activities of polyphenol-rich extract from OMWW, A009, in cooperation with chemotherapy on two breast cancer cell lines, namely, BT459 and MDA-MB-231, in a cardio-oncology perspective. The effects of A009 on cardiac cells were also investigated with and without chemotherapeutic agents. Cell viability was determined on BT459 and MDA-MB-231 (i.e., breast cancer cells) and H9C2 (i.e., rat cardiomyocytes) cells, using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. A spheroids assay was used as a 3D *in vitro* model on BT459 and MDA-MB-231 cells. For *in vivo* studies, the murine sponge assay of angiogenesis was used as a model of breast cancer-associated vascularization. The embryo of *Danio rerio* (zebrafish) was used to detect the cardioprotective activities of the OMWW. We found that the A009 extract exhibited antiangiogenic activities induced by breast cancer cell supernatants and increased T-cell recruitment *in vivo*. The combination of the OMWW extracts with doxorubicin or 5-FU limited BT459 and MDA-MB-231 cell viability and the diameter of 3D spheroids, while mitigating their toxic effects on the rat H9C2 cardiomyocytes. Cardioprotective effects were observed by the combination of OMWW extracts with doxorubicin in zebrafish embryos. Finally, in human cardio myocytes, we observed 5-FU-induced upregulation of the inflammatory, senescence-associated cytokine IL6 and

p16 genes, which expression was reduced by OMWW treatment. Our study demonstrates that the polyphenol-rich purified OMWW extract A009 combined with cancer chemotherapy could represent a potential candidate for cardiovascular protection in breast cancer patients, while increasing the effects of breast cancer chemotherapy.

**Keywords:** chemotherapy, breast cancer, polyphenol, olive, cardiomyocyte

**GRAPHICAL ABSTRACT** | The cartoon summarized the major approaches and insights of the manuscript: **(A)** the possibility to recover waste material from extra-virgin olive oil (EVOO) processing that allows the repurposing of polyphenol-rich extracts characterized by **(B)** antiangiogenic activities *in vivo*, antiproliferative activities *in vitro* on BC cell lines **(C)**, cardioprotective activities on rat and human cardiomyocytes (HCMs) **(D)**, and *in vivo* on the zebrafish embryo heart **(E)**.

## INTRODUCTION

Together with cardiovascular diseases, cancer still accounts as a major cause of death in the world (1, 2). Breast cancer (BC) is the fifth most prevalent cause of cancer death worldwide and is the most common malignancy among women (3). BC is characterized by the presence of several different subtypes, which are generally classified as hormone receptor (HR)-positive and human epidermal growth factor receptor 2 (HER2)-overexpressing BCs or triple negative BC. The presence of the markers has allowed the development of targeted therapies. Tumors without the expression of HR or HER2 are classified as triple-negative BC (TNBC). TNBC has a higher mortality rate than HR-positive or HER-2-overexpressing BC because of its high recurrence rate and metastatic potential (4).

Among the current strategies for the treatment of TNBC, chemotherapy represents the major option (5, 6). Taxanes (e.g., paclitaxel and docetaxel) and anthracyclines (e.g., doxorubicin and epirubicin) are usually the main choice (7), in combination with platinum (e.g., carboplatin), antimetabolites [e.g., capecitabine, similar to 5-fluorouracil (5-FU)] and/or alkylating agent (e.g., cyclophosphamide); however, their possible toxicity, low aqueous solubility, and rapid *in vivo* clearance can represent a limit (7, 8). All these agents are often used in combination with targeted therapy.

Despite the great medical and pharmaceutical advances, these limitations remain a big challenge. According to the Food and Drug Administration (FDA), about 1 million of severe adverse drug events (ADEs) were reported in only 1 year in the United States, including death (9). Chemotherapy-induced cardiotoxicity is one of the most common ADEs and can cause more or less serious manifestations, such as changes in ECG, arrhythmia, bradycardia, tachycardia, and heart failure, which lead to an increase in morbidity and mortality (7, 9). In this complex contest, prevention still remains the most promising approach for all types of cancer. Natural products or agents derived from foods and beverages (or their synthetic analogs) have been found to exert antitumor and tumor-preventive activities in diverse preclinical settings, and some are currently employed in the clinic. Among them, phenolic compounds have gained the attention of the scientific community, thanks to their plethora of beneficial effects on health, that include antibacterial, anti-inflammatory, and anticancer activities. Also, several preclinical studies, including those published by our research group, showed that diverse phytochemicals, while synergizing with chemotherapeutic drugs, have cardioprotective activity (10, 11).

Southern European countries have lower incidence of cancer and cardiovascular disease than northern European countries or the United States. The Mediterranean diet has been proposed as the main protective factor for this benefit (12). In this context, angioprevention is an important concept to consider, since angiogenesis prevention through bioactive compounds present in the Mediterranean diet components could explain in part the chemopreventive effect of this diet model in cancer (13–17). Extra-virgin olive oil (EVOO) is a major component of the Mediterranean diet, with numerous beneficial effects,

which concern the ability to prevent diseases that can be linked to oxidative damage, such as neurodegenerative diseases, cancer, and cardiovascular diseases (18). EVOO protective role is due to its enriched content in phytochemicals: the main fraction (95–97%) is the lipophilic one, which is represented by both monounsaturated and polyunsaturated fatty acids (i.e., omega-3 and omega-6) (19). The polar fraction is mainly represented by polyphenolic compounds like oleuropein, tyrosol, and hydroxytyrosol, which possess strong anti-inflammatory and antioxidant properties (20). A major issue within the industrial processing of EVOO is the generation of large amount of liquid waste product, including, olive mill wastewater (OMWW) (21, 22). The high content of pollutants within the waste requires special disposal and cost-effective procedures that significantly impact both the health environment and the industrial management. In contrast, it has been found that OMWW is rich in polyphenolic compounds, endowed with antibacterial and antioxidant activities, thus representing a valid product to be considered in scientific research (23).

We previously reported that the A009 polyphenol-rich extracts, purified from OMWW, exhibit chemopreventive and angiopreventive properties, *in vitro* and *in vivo*, in different cancer types (e.g., lung, colon, and prostate cancer cells) and endothelial cells (11, 24–27).

In this study, we investigated the A009 effect on tumor growth of BC cells, alone or in combination with a chemotherapeutic agent. In addition, we examined the potential A009 cardioprotective activity, against chemotherapy-induced cardiovascular damages, using both *in vitro* and *in vivo* models (i.e., *Danio rerio* and *Mus musculus*). In this study, we focused on doxorubicin and 5-FU, which are very prominent, highly active anticancer drugs, however, endowed with cardiotoxic effects. Work flow is described in the **Graphical Abstract**.

## MATERIALS AND METHODS

### Chemicals

5-Fluorouracil was purchased from Sigma-Aldrich and was dissolved in dimethyl sulfoxide (DMSO) and used for *in vitro* experiments as detailed below. Doxorubicin hydrochloride (Doxo) was purchased from Abcam and was dissolved in Milli-Q water. 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) was purchased from Sigma-Aldrich. The synthetic hydroxytyrosol (Hyt),  $\geq 98\%$  in purity, was purchased from Cayman Chemicals (Ann Arbor, MI, USA). Hyt was dissolved in ethanol (EtOH). DMSO and EtOH vehicles were used as controls.

### Preparation of A009 Extracts

Olive oil mill wastewaters were kindly provided by Agriturismo Fattoria La Vialla (Castiglion Fibocchi, Arezzo, Italy) and used to obtain the phenol-rich purified extract A009 (Patent No. 1420804; No. 1420805). The experiments were performed using the extract A009. The extraction procedures of A009 obtained from OMWW and its polyphenol content have been previously

described (24). The polyphenol content of the A009 extract is shown in **Supplementary Table 1**.

## Cell Line Culture and Maintenances

The human metastatic BC cells, e.g., MDA-MB-231 (purchased from ATCC), were maintained in the Dulbecco's Modified Eagle's Medium (Gibco-BRL) supplemented with 10% fetal bovine serum (FBS) (Euroclone), 2 mM L-glutamine (Euroclone), 100 U/ml penicillin, and 100 µg/ml streptomycin (Euroclone), at 37°C, 5% CO<sub>2</sub>. The human BC cell line BT549 (purchased from ATCC) was grown in Roswell Park Memorial Institute (RPMI) 1640 supplemented with 10% FBS, 2 mM L-glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin, and 0.023 U/ml insulin at 37°C, 5% CO<sub>2</sub>. The human cardiomyocytes (HCMs, purchased by PromoCell) cells were maintained in the Myocyte Growth Medium (PromoCell) plus Myocyte supplements mix (PromoCell), in addition to 10% FBS, 2 mM L-glutamine, 100 U/ml penicillin, and 100 µg/ml streptomycin, at 37°C, 5% CO<sub>2</sub>. The rat cardiomyocytes cell line H9C2 (purchased by PromoCell) was maintained in DMEM-F12, supplemented with 10% FBS, 2 mM L-glutamine, 100 U/ml penicillin, and 100 µg/ml streptomycin. All the cell lines used in the study were routinely checked for eventual mycoplasma contamination, before being used.

## Generation of Conditioned Media

Conditioned media (CM), for subsequent *in vivo* studies, was obtained from the BT459 BC cell line. Briefly,  $3 \times 10^6$  BT459 were seeded into t100 Petri dishes (Corning) in RPMI 1640 supplemented with 10% FBS, 2 mM L-glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin, and 0.023 U/ml insulin at 37°C, 5% CO<sub>2</sub>. When cells reached 80% of confluency, cells were starved for 48 h in 10 ml serum-free RMPI medium. Finally, CM were collected, residual cells and debris were discarded, by centrifugation, and concentrated with Centricon devices (Millipore, Temecula, CA) with a 5 kDa membrane pore cutoff.

## *In vivo* Angiogenesis Sponge Assay as a Model of Breast Cancer-Associated Angiogenesis

To use a rapid model of breast cancer-associated angiogenesis *in vivo* (28–30), the ability of A009 (1:250) to inhibit vascularization, induced by CM of BC cell lines, was investigated using the UltiMatrix (Biotechne) Matrigel sponge assay in mice. Briefly, liquid UltiMatrix (10 mg/ml) was mixed with 50 µg of total protein BT459-concentrated CM, alone or in combination with the A009 extract (1:250 dilution) and inoculated in cold liquid form, which polymerizes *in vivo*. UltiMatrix alone or UltiMatrix supplemented with a cocktail of proangiogenic factors VEGF, TNFα and Heparin (VTH) (100 ng/ml vascular endothelial growth factor (VEGF)-A, 2 ng/ml tumor necrosis factor (TNF)-α, and 25 U/ml heparin) were used as negative and positive controls, respectively. Each mixture was brought to a final volume of 0.6 ml and injected subcutaneously into the right and left flanks of 6–8-week-old C57/BL6 female mice (Charles River Laboratories, Calco (Lecco), Italy) with a cold syringe. All animals were housed in a conventional animal facility

with 12 h light/dark cycles and fed *ad libitum*. Manipulation of animals was performed in accordance with the Italian and European Community guidelines (D.L. 2711/92 No.116; 86/609/EEC Directive), the 3 R's declaration, and approved by the institutional ethics committee. All the procedures applied were approved by the local animal experimentation ethics committee (ID# #06\_16 Noonan) of the University of Insubria and by the Health Ministry (ID#225/2017-PR).

Groups of 3–7 mice were used for each treatment. At body temperature, the UltiMatrix polymerizes to a solid gel and becomes vascularized in response to angiogenic substances. Four days following injection, the gel plugs were recovered and divided into two parts. One half was formalin-fixed, paraffin-embedded to generate paraffin blocks processed for histological analysis; the other half from gel plugs was minced and diluted in water to measure the hemoglobin content with a Drabkin's Reagent Kit (Sigma-Aldrich), and part was mechanically processed for the subsequent flow cytometry analysis.

## Immunohistochemistry Analysis of UltiMatrix Sponges

All the processing for the immunohistochemistry analysis on the UltiMatrix sponges were performed by the Unit of Pathological Anatomy, IRCCS MultiMedica, Milan, Italy, by a routine system on an automated immunostainer (BenchMark ULTRA IHC/*in situ* hybridization System, Ventana-Roche Group, Basel, Switzerland). Hematoxylin and Eosin-stained sections were used to acquire micrographs, at 40× magnification.

## Flow Cytometry Analysis for Cell Infiltrate in the UltiMatrix Plugs

Part of the recovered UltiMatrix plugs were mechanically processed by scissors, then placed into 70 mm cell strainers (BD Biosciences), and pressured with a syringe swab. The cell suspension obtained was used for the flow cytometry analysis to detect the immune cell infiltrate. Cells were stained for 30 min at 4°C, at dark, with the following fluorophore-conjugated antimouse antibodies, all purchased from BD Biosciences: CD45-BUV395, F4/80-PECF594, CD3e-BB700, and NK1.1-BV650. For fluorescence-activated cell sorting (FACS) analysis, viable cells were gated according to physical parameters (FSC/SSC). Following the gating of CD45<sup>+</sup> cells, immune cells were identified as follows: CD45<sup>+</sup>:F4/80<sup>+</sup> cells (macrophages), CD3<sup>+</sup> cells (total T cells), and CD3<sup>−</sup>NK1.1<sup>+</sup> cells (total NK cells).

## Assessment of Combination Effect of Chemotherapy and A009 on Breast Cancer Cell Lines and Rat Cardiomyocytes by MTT Assay

To investigate whether the A009 extract could synergize with chemotherapy, cell viability of the BC cell lines MDA-MB-231 and BT549 was evaluated by the MTT assay (**Supplementary Table 2**). The  $2 \times 10^3$  cells of BT549 and MDA-MB-231 BC cell lines were seeded in 96-well plates and, after adhesion, treated with A009 extract (dilution 1:800) and Hyt (dilution 1:800) for 24 h. The medium was then substituted

with the chemotherapy drug 5-FU 100  $\mu$ M or Doxorubicin 1  $\mu$ M, alone or in combination with A009 or Hyt for 48 and 72 h. At each time point, media were replaced with fresh complete medium, supplemented with 0.5 mg/ml MTT reagent, and then incubated for 3 h at 37°C with 5% CO<sub>2</sub>. This colorimetric assay is based on the reduction of a yellow tetrazolium salt (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide or MTT) to purple formazan crystals by metabolically active cells. The viable cells contain NAD(P)H-dependent oxidoreductase enzymes that reduce the MTT to formazan. MTT was removed, and formazan crystals were dissolved using 100% DMSO. The darker the solution, the greater the number of viable, metabolically active cells. The absorbance was recorded at 570 nm wavelength with the microplate spectrophotometer SpectraMax M2 (Molecular Devices, Sunnyvale, CA). To evaluate the effects of the A009 extracts on chemotherapy-induced cardiotoxicity, the same experiment was repeated on rat cardiomyocytes H9C2 cells (**Supplementary Table 2**).

## Generation of Tumor Spheroids

We investigated the capability of the A009 extract to synergize with chemotherapy, in reducing the generation of BC tumor spheroids. BT459 or MDA-MB-231 cells were cultured in 20  $\mu$ l hanging drops at a density of  $4 \times 10^3$  cells/drop, in complete RPMI medium, with or without treatment. After spheroids formation, which typically occurs within 24 h, the spheroids were transferred to 96-well plates, containing 100  $\mu$ l/well of fresh culture medium with or without treatment (one spheroid/well), previously coated with 2% agar and growth on the bottom of 60 mm tissue culture dish, at 37 °C and 5% CO<sub>2</sub>. BT459 and MDA-MB-231 spheroids were treated with the A009 extract + 5-FU 100  $\mu$ M combination, or the A009 extract + Doxo 1  $\mu$ M combination, or A009 extract or 5-FU alone. Growth of the spheroidal colonies was monitored for the following days, replacing culture medium and treatments, with fresh ones, each 48 h. Images were acquired at 3, 6, and 12 days, following spheroid generation and treatments. Untreated and treated spheroids' area was measured, for each time point, using the ImageJ software and normalized for the respective area at day 3. The diameter was calculated based on the spheroid area, using the  $d = \sqrt{(4A/\pi)}$  formula. Finally, the average area, between treatment groups, was compared.

## In vivo Studies on Zebrafish Embryos

To evaluate the cardioprotective effect of the A009 extract, we used the embryos of *Danio rerio* (zebrafish), a robust animal model for cardiovascular diseases (31–33). Zebrafish eggs were incubated at a temperature of  $26 \pm 1^\circ\text{C}$ , in a 12:12 h light:dark regime. Developmental stages were identified according to Kimmel et al. (34). Eggs were collected and washed two times with ISO-water (80 mM CaCl<sub>2</sub>, 20 mM MgSO<sub>4</sub>, 30.8 mM NaHCO<sub>3</sub>, and 3.09 mM KCl) according to DIN ISO 150888 (International Organization for Standardization (ISO), 2009). All experiments were performed on zebrafish embryos exposed to the indicated agents for 24, 48, and 72 h post fertilization (hpf). Ten fertilized eggs were maintained in 24-well plates, with a proportion of 1 embryo/2 ml of solution. Embryos received A009 (dilutions 1:1,000 or 1:500), alone or in

combination with the cardiotoxic agent doxorubicin (3  $\mu$ g/ml) or left untreated. Embryo development was monitored at 48 and 72 hpf using an inverted stereomicroscope (Leica), by tracing the development of eyes, heartbeat, blood circulation, pigmentation, body shape malformations, edemas, detachment of the tail, and delay in development. The effect on embryo viability was determined by counting the number of dead embryos per experimental condition. Several parameters to trace the treatment induced congenital embryo abnormalities were monitored as listed in **Supplementary Tables 3, 4**. Congenital embryo abnormalities monitored included ischemia in the yolk sack (IS-YS), malformation of the heart (M.HT), ischemia in the tail (IS-TA), malformation of the tail (MT), yolk sack malformation (YS-DE), swim bladder malformation (SWB-DE), pericardial edema (PE), and ischemia in the brain (IS-BR).

## Quantitative Real-Time PCR

Total RNA was extracted from HCM exposed to A009 (dilution 1:800) alone or in combination with 5-FU 100  $\mu$ M for 24 h. The TRIzol method was used, following separation with chloroform precipitation of RNA with isopropanol (Sigma-Aldrich). The RNA pellet was washed twice with 75% ethanol (Sigma-Aldrich) and resuspended in nuclease-free water. RNA concentration was determined using the Nanodrop Spectrophotometer ND-1000 (Thermo Fisher Scientific). Reverse transcription was performed using the SuperScript VILO cDNA synthesis kit (Thermo Fisher Scientific), starting from 1,000 ng of total RNA. Quantitative real-time PCR was performed using SYBR GreenMasterMix (Applied Biosystems) on the QuantStudio 6 Flex RealTime PCR System Software (Applied Biosystems). All reactions were performed in duplicate. The relative gene expression was indicated as relative to nontreated cells, normalized to the housekeeping gene 18S. IL-6 (Fw-AGACAGCCACTCACCTCTTCAG, Rv-TTCTGCCAGTGCCCTCTTTGCTG), p16 (Fw-CTCGTGCTGATGCTACTGAGGA, Rv-GGTCCGGCGCAGTTGGGCTCC), and the housekeeping 18S (Fw-CGCAGCTAGGAATAATGGAATAGG, Rv CATGGCCTCAGTTCCGAAA) primers, for qPCR, were designed using the NCBI Primer BLAST tool and purchased from Integrated DNA Technologies (IDT, Coralville, IA, USA).

## Statistical Analysis

The statistical significance between multiple datasets was determined using the GraphPad Prism software v9. Flow cytometry data were analyzed using the FlowJo software, v10. Data are expressed as means  $\pm$  SEM, one-way ANOVA, followed by the Tukey's *post-hoc* test. The  $p \leq 0.05$  were considered statistically significant.

## RESULTS

### A009 Inhibits Angiogenesis *in vivo*

To evaluate the effect of the extract A009 (dilution 1:250) on angiogenesis, a hallmark of cancer, induced by CM of BC cells *in vivo*, a Matrigel sponge assay was performed in C57/BL6 female mice. We found that the A009 extract (1:250) was able to reduce the angiogenic activities exerted by the BT549 BC CM, as revealed by the colorimetric analysis of

the excised UltiMatrix plugs (**Figure 1A**). The A009 extract (1:250) was able to reduce the total hemoglobin content in the treated plugs, as compared with those containing the BT549 BC CM alone, in a statistically significant dependent manner (**Figure 1A**). Proangiogenic recruitment of endothelial cells was also decreased as demonstrated by histological staining (**Figure 1C**). Given the immune-modulatory properties of the A009 extract, we tested its ability to enhance immune cell number in the exposed sponge, following excision. We found that the A009 extract (1:250) was able to increase the infiltration of T cells in treated plugs, as compared with those containing the BT549 BC CM alone; in a statistically significant manner (**Figure 1B**), macrophages and NK cells are non-significantly modified (**Supplementary Figure 1**).

### Effect of A009 on Cell Viability of BC Cell Lines in 2D and 3D Models *in vitro*

The effect of the A009 extract on tumor cell viability was investigated using the MTT assay. BT549 and MDA-MB-231 BC cell lines were pretreated with A009 extract (dilution 1:800) or Hyt (dilution of the major polyphenol present in the A009 extract, 1:800) for 24 h. The medium was then replaced with the chemotherapeutic drug Doxo 1  $\mu$ M or 5-FU 100  $\mu$ M, alone or in combination with the A009 extract or Hyt. Cells were treated for 48 and 72 h. The schedule of treatments and pretreatments is depicted in **Supplementary Figure 2**. Cell metabolic activity assessed by MTT of BT549 and MDA-MB-231 cells, receiving pretreatment with the extract A009 or Hyt, followed by the co-administration of these compounds with the chemotherapy drug 5-FU, was reduced compared with that of the cells receiving the 5-FU alone (**Figures 2A,B**). The same effect occurs on BT549 and MDA-MB-231 (**Figure 3B**), when treated with the A009 extract in combination with doxorubicin (**Figures 3A,B**). These results showed that the addition of chemotherapy to the A009 extract acts in an additive way reducing BC cell viability *in vitro*. We translated our results from a 2D to a 3D *in vitro* model of BC, by generating tumor spheroids, further treated following the same schedule applied for the 2D models. We observed that the combination of the A009 extract (1:800) with the chemotherapeutic agents 5-FU or Doxo synergized in blocking the generation of BC spheroids that morphologically appear less stable and with reduced diameter, within the time frame of treatments (**Figures 4A–D**).

### Cardioprotective Effect of A009 on Rat Cardiomyocytes

Based on our previous published article on the cardioprotective properties of the A009 extracts against chemotherapy-induced damages in models of prostate cancers (11), we also tested whether a similar scenario could be observed with chemotherapeutic agents used in BC treatment, such as 5-FU and Doxo. We observed that the rat cardiomyocyte cell line H9C2 exhibited less reduced cell proliferation, when co-treated with the A009 + 5-FU (**Figure 5**) or A009 + Doxo (**Figure 6**), both at 48 and 72 h, as compared to 5-FU or Doxo alone. 5-FU and Doxo were toxic, while A009 or Hyt alone did not show

**FIGURE 1 |** Effects of the A009 extract on angiogenesis and immune cell infiltration *in vivo*. The effects of the A009 on angiogenesis, induced by CM of BC cell lines, and immune cell infiltration *in vivo*, was evaluated by the UltiMatrix Matrigel sponge assay. **(A)** Determination of the hemoglobin content in the excised plugs, using the Drabkin's assay and visual inspection of excised pellets; **(B)** determination of T-cell infiltration, detected as CD3<sup>+</sup> cells, in the plugs by flow cytometry. Data are shown as mean  $\pm$  SEM, one-way ANOVA, \* $p$  < 0.05 and \*\* $p$  < 0.01. VTH (vascular endothelial growth factor (VEGF), tumor necrosis factor (TNF)- $\alpha$ , heparin), CM BTH (CM BT549 + heparin), A009 extract. Hemoglobin is decreased by A009 and T-cell infiltrates are increased. **(C)** Histological examination of pellets. Sections of paraffin embedded plugs were stained with hematoxylin eosin. VTH: VEGF-TNF- $\alpha$ -heparin containing UltiMatrix show angiogenesis. Pellets with BTH conditioned media show angiogenesis with many vessels. Pellets with A009 in addition to BTH CM show reduced angiogenesis with few vessels.

cardiotoxicity. In addition, the co-administration of A009 or Hyt with the chemotherapy drugs does not increase damage induced by the drugs, Hyt + 5-FU after 48 and 72 h, and both Hyt + Doxo and A009 + Doxo after 48 and 72 h.

### Cardioprotective Effects of A009 Extract in Zebrafish Embryos

We extended our *in vitro* results to the zebrafish (*Danio rerio*) animal model. Zebrafish embryos were exposed to

**FIGURE 2 |** Effects of the A009 extract in combination with 5-fluorouracil (5-FU) on breast cancer cell lines. BT549 (A) and MDA-MB-231 (B) cells were pretreated with extract A009 (dilution 1:800) or hydroxytyrosol (Hyt) (same concentration as that present in the 1:800 diluted A009 extract), for 24 h. Later, the medium was replaced with 5-FU 100  $\mu$ M alone or in combination with A009 or Hyt for 48 and 72 h. Proliferation was detected by the MMT assay at the indicated time points. The experiments were performed in quadruplicate and repeated two times. Results are expressed as the mean of the absorbance normalized on the T0  $\pm$  SEM, one-way ANOVA, \* $p$  < 0.05, \*\* $p$  < 0.01, \*\*\* $p$  < 0.001, and \*\*\*\* $p$  < 0.0001. A009 activity was enhanced by addition of chemotherapy towards breast cancer cells.

**FIGURE 3 |** Effects of the A009 extract in combination with doxorubicin on breast cancer cell lines. BT549 (A) and MDA-MB-231 (B) cells were pretreated with extract A009 (dilution 1:800) or Hyt (same concentration as that present in the 1:800 diluted A009 extract), for 24 h. Later, the medium was replaced with doxorubicin 1  $\mu$ M alone or in combination with A009 or Hyt for 48 and 72 h. Proliferation was detected by the MMT assay at the indicated time points. The experiments were performed in quadruplicate and repeated two times. Results are expressed as the mean of the absorbance normalized on the T0  $\pm$  SEM, one-way ANOVA, \* $p$  < 0.05, \*\* $p$  < 0.01, and \*\*\*\* $p$  < 0.0001. A009 activity was enhanced by addition of chemotherapy toward breast cancer cells.

**FIGURE 4 |** Effects of the combination A009+chemotherapy on breast cancer spheroids. Single spheroids were generated by culturing  $4 \times 10^3$  BT549 or MDA-MB-231 cells in nonadherent conditions. BT549 (A,B) and MDA-MB-231 (C,D) spheroids were treated with the combination of A009 extract + 5-FU or Doxo, A009 or drugs alone, for 3, 6, and 12 days. During the treatment kinetic, spheroid diameters were detected, and spheroid macrophotographs were captured. The experiments were performed in quadruplicate and repeated two times. Scale bar = 200  $\mu\text{m}$ . Data are shown as mean  $\pm$  SEM, two-way ANOVA,  $**p < 0.01$ ,  $***p < 0.001$ , and  $****p < 0.0001$ . A009 combinations with chemotherapy reduced size of breast cancer cell spheroids.

Doxo, alone or in combination with the A009 extract (dilution 1:1,000 or 1:500). We observed that the treatment of zebrafish embryos with doxorubicin (3 g/ml) significantly reduced their cardiac area at 48 and 72 h of treatment (Figures 7A,B). The co-treatment with A009 was able to reverse the doxorubicin-induced cardiotoxic effect, in terms of cardiac area, following 48 and 72 h of treatment (Figures 7A,B). The polyphenolic concentrate alone does not change the viability of the embryos.

Furthermore, we observed that co-treatment of embryos with the A009 extract and doxorubicin resulted in decreased

numbers of embryos displaying congenital abnormalities, when compared with embryos treated with doxorubicin alone (Supplementary Tables 3, 4).

### Effect of A009 on Inflammation and Induction of Senescence Associated With Chemotherapy in Human Cardiomyocytes

Chemotherapy is often associated with damages to the heart that result in exacerbated cardiac inflammation and generation of senescent phenotype in cardiomyocytes. Il6 is among

the cytokines involved in the cardiac inflammation and participating to the induction of the senescent-associated secretory phenotype (SASP), while p16 is a senescence marker. We investigated the effect of A009 on IL-6 and p16 gene expression, both molecules linking inflammation and senescence, following chemotherapy-induced (i.e., 5-FU) cardiac damages, on HCM cells. We found that HCM cells, exposed to the combination of A009 extract (1:800) and 5-FU 100  $\mu$ M, exhibit decreased transcript levels of IL-6 (**Figure 8A**) and p16 (**Figure 8B**), as compared to HCM treated with 5-FU alone, in a statistically significant dependent manner.

## DISCUSSION

Chemotherapy, alone or in combination with other therapies (i.e., targeted, antiangiogenic therapies), along with surgery and radiotherapy is still a major option in BC treatment. However, cancer chemotherapy-induced cardiotoxicity remains a relevant obstacle, thus limiting the therapeutic options (alone or in combination) for cancer patients (10, 35–37). This largely impacts on the management of oncologic patients, requiring more efforts to overcome the generation of side effects, following cancer chemotherapy that remains the treatment of election (10, 35–37). With the knowledge of such a relevant unmet clinical

**FIGURE 7 |** Cardioprotective effects of A009 extract in zebrafish embryos. The cardioprotective effects of the A009 extract on chemotherapy-induced cardiotoxicity was investigated in zebrafish embryos. All experiments were performed on zebrafish embryos exposed to doxorubicin (3  $\mu$ g/ml) alone, A009 (dilution 1:1,000, 1:500), or the combination of doxorubicin ( $\mu$ g/ml) and A009 (dilution 1:1,000, 1:500) for 48 h (A) and 72 h (B) post fertilization (hpf). Embryo micrographs for all the experimental conditions are shown. Data for cardiac area are shown as fold% increased over control. Data are shown as mean  $\pm$  SEM, one-way ANOVA, \*\* $p < 0.01$  and \*\*\* $p < 0.001$ . DOX, doxorubicin; A009 batch extract; NT, not treated. A009 combinations with chemotherapy were protective toward the heart.

need, together with the identification of robust biomarkers able to predict chemotherapy-induced cardiovascular effects, prevention remains the most accessible option to manage such an issue (10, 35, 36), and cardio-oncology is a flourishing field of investigation (38, 39).

Polyphenols account as the major dietary-derived molecules endowed with beneficial effects on human health, based on

their ability to target tumor cells, while sparing or recovering damaged normal/healthy cells. In this context, EVOO accounts as one of the most abundant dietary sources of polyphenols, within the Mediterranean diet. Interestingly, also the waste products derived by EVOO processing have been reported to be rich in polyphenols with beneficial health effects, such as hydroxytyrosol. We have previously demonstrated that the

polyphenol-rich OMWW extract, A009, from EVOO is endowed with antiangiogenic properties and chemopreventive activities in the context of colon and prostate cancers, both *in vitro* and *in vivo*. Recently, we also showed, in *in vitro* and *in vivo* models of prostate cancer, that the combination of the A009 extract with chemotherapy resulted in increasing chemopreventive and antitumor activities, while mitigating the chemotherapy-induced damages to cardiomyocytes and mice hearts.

Starting from our previous results of antiangiogenic effects of the A009 extracts, in this study, we tested the ability of A009 to limit angiogenesis, a hallmark of cancer, *in vivo*, induced by CM from the BT549 BC cell line in a Matrigel sponge model that we contributed to develop (27–29). We found that the A009 extract limits angiogenesis *in vivo*, induced by factors present in the BT549 cell CM. We also observed that the BT549 CM sponges from mice treated with the A009 extract show increased infiltration of CD3<sup>+</sup>T cells, suggesting a potential contribution of the OMWW extract in the recruitment of immune cells.

We then tested the capability of the combination of the A009 extract with chemotherapeutic agents clinically employed in BC, to act on BC cell proliferation. We found that both the BT549 and MDA-MB-231 cells, following exposure to the A009 + 5-FU or A009 + Doxo combination, exhibited reduced cell proliferation, as compared with those treated with A009 alone. We observed additive effects by treating BT459 and MDA-MB-231 cell spheroids, with the A009 + drug combination. These results show that the combination of chemotherapy with the A009 extract further reduces BC cell viability *in vitro*.

A peculiar capability of polyphenols resides in their ability to target transformed malignant cells (40) also cooperating with chemotherapeutic agents (11, 40, 41), while sparing healthy cells or recovering healthy cells undergoing stress conditions and cellular damages (42–44). Based on this evidence and on our previous published article on the cardioprotective properties of the A009 extract against chemotherapy-induced damages, in models of prostate cancers, we tested whether

a cardio-oncological prevention scenario could be observed, using chemotherapeutic agents used for BC treatment, such as doxorubicin and fluoropyrimidines. The combination of A009 extract to chemotherapy mitigate the effects of reduced cell proliferation, mediates by 5-FU alone on rat cardiomyocytes. We found that this cardioprotective effect of the A009 extract occurs also *in vivo*: zebrafish embryos exposed to A009 extract + Doxo combination show rescue of cardiac area, as compared with those treated with Doxo alone.

OMWW extracts are not toxic to the animals, and in a cohort of healthy, individuals were highly tolerated with no toxicity (11).

Inflammation represents a peculiar hallmark of chronic diseases, such as cancer, metabolic, and cardiovascular disorders (45–48). Chemotherapy-induced cardiovascular side effects also include exacerbated inflammation, together with induction of cell senescence and of an SASP. We previously demonstrated that cardiovascular toxicities associated with the anticancer agent 5-FU include the induction of a senescent phenotype in HCMs and endothelial cells (49).

IL-6 accounts as a relevant cytokine in the inflammatory process (50) and is highly represented in the cytokine milieu characterizing the SASP phenotype (51, 52). In line with this evidence, we found that HCMs treated with 5-FU, have increased transcript levels of IL-6 and the senescence marker p16. We observed that the combination of the A009 extract with 5-FU can reduce the expression level of IL-6 and p16, induced by the 5-FU. This suggests the potential capability of the A009 extracts to exert cardioprotective activities also acting on the inflammation/senescence pathways in cardiomyocytes exposed to chemotherapeutic agents.

## CONCLUSION

Our study suggests that in a cardio-oncological prevention perspective, a polyphenol-rich purified OMWW extract A009 combined with cancer chemotherapy, could represent a potential candidate for cardiovascular protection in patients with BC, while increasing effects of BC chemotherapy.

Chemotherapy and targeted therapies have significantly improved the prognosis of oncology patients. However, these antineoplastic treatments may also induce adverse cardiovascular effects, which may lead to acute or delayed onset of cardiac dysfunction. These common cardiovascular complications, commonly referred to as cardiotoxicity, not only may require the modification, suspension, or withdrawal of life-saving antineoplastic therapies, with the risk of reducing their efficacy, but can also strongly impact the quality of life and overall survival, regardless of the oncological prognosis. The onset of cardiotoxicity may depend on the class, dose, route, and duration of administration of anticancer drugs, as well as on individual risk factors. Importantly, the cardiotoxic side effects may be reversible, if cardiac function is restored upon discontinuation of the therapy, or irreversible, characterized by injury and loss of cardiac muscle cells. Subclinical myocardial dysfunction induced by anticancer therapies may also subsequently evolve in symptomatic congestive heart failure. Hence, there is an urgent need for cardioprotective therapies to reduce the clinical and subclinical cardiotoxicity onset and progression and to limit the acute or chronic manifestation of cardiac damages. In this review, we summarize the knowledge regarding the cellular and molecular mechanisms contributing to the onset of cardiotoxicity associated with common classes of chemotherapy and targeted therapy drugs. Furthermore, we describe and discuss current and potential strategies to cope with the cardiotoxic side effects as well as cardioprotective preventive approaches that may be useful to flank anticancer therapies.

**Keywords:** cardiotoxicity, cardioncology, cardiomyocyte death, cardiomyocyte dysfunction, cardiomyocyte survival, chemotherapy, targeted therapy, cardioprotection

## INTRODUCTION

The introduction of antineoplastic drugs has been a turning point for prognosis improvement in oncology patients. However, a large number of chemotherapeutic agents have adverse cardiovascular effects, leading to acute or delayed onset of cardiac dysfunction, commonly referred to as cardiotoxicity. Although the definition of cardiotoxicity is not universally accepted, in clinical practice, cardiotoxicity commonly indicates a decline in patients' cardiac function measured as

left ventricle ejection fraction (LVEF). Various organizations and clinical committees defined cardiotoxicity using different threshold changes in LVEF [reviewed in (1)]. Treatment with anthracyclines, namely the chemotherapy class of drugs that generated the most concerns about cardiotoxicity, is associated with an incidence of cardiac dysfunction ranging between 2% and 48% [reviewed in (2–7)]. The Cardiac Review and Evaluation Committee (CREC), a retrospective study aiming at the evaluation of the cardiotoxicity of the anti-HER2 agent trastuzumab with or without concomitant anthracycline treatment, defined cardiotoxicity as a reduction in LVEF of at least 5% to below 55% with concomitant signs or symptoms of congestive heart failure (CHF), or a decrease in LVEF of at least 10% to below 55% without associated signs or symptoms (8). Although the assessment of LVEF is a well-established clinical procedure for the early recognition of cardiotoxic side effects to prevent irreversible cardiac damage and heart failure (HF), a reduction in LVEF may not be an effective parameter to detect a subclinical myocardial dysfunction that subsequently evolves in a symptomatic CHF (9) [reviewed in (1, 10)].

During the last decades, the cardiotoxic effects of several classes of chemotherapy drugs (anthracyclines, fluoropyrimidines, taxanes, and alkylating agents) and targeted therapies (targeting monoclonal antibodies and kinase inhibitors) were documented, and the underlying molecular mechanisms were investigated to suggest and develop potential strategies to avoid or reduce these effects (Table 1). Based on retrospective pathophysiological analysis of cancer patients with HF after chemotherapy, cardiotoxic side effects can be defined as irreversible (type I) or reversible (type II) [reviewed in (11, 12)]. Irreversible cardiotoxicity (type I) is usually observed in anticancer regimes causing injury and loss of cardiac myocytes. These effects are mainly observed after administration of anthracyclines and alkylating drugs, and to a lesser degree with fluoropyrimidines. According to the class of anticancer agents, the underlying mechanisms may involve cardiomyocyte-intrinsic and/or indirect mechanisms. For example, anthracyclines are associated with a high incidence of HF as consequence of irreversible cardiac damages through impairment of cardiomyocyte-intrinsic mechanisms leading to cell death [reviewed in (5, 7, 13–15)]. Despite administration of alkylating drugs and fluoropyrimidines may also cause cardiomyocyte death and thus irreversible cardiac damage, the main mechanism appears to be mediated by a vasculature dysfunction and/or thromboembolic ischemia. However, anticancer agents may also impair cardiomyocyte function without inducing cell death. This type of cardiac dysfunction is typically reversible and is associated with a lower incidence of HF (type II cardiotoxicity). Mechanistically, it has been suggested that reversible cardiotoxicity may be consequent to the deregulation of cardiomyocyte-intrinsic mechanisms and/or alteration of other cardiac populations and extracellular factors, in particular paracrine factors, in turn influencing cardiomyocyte function [reviewed in (4)]. Targeting monoclonal antibodies or tyrosine kinase inhibitors (TKIs) are typically associated with reversible cardiac damages, and their adverse effects derive by the signaling impairment of cardioprotective factors for

cardiomyocytes, such as Neuregulin-1 (NRG1), or for other cardiac cell populations, such as vascular endothelial growth factor (VEGF), and platelet-derived growth factor (PDGF) [reviewed in (13, 16)].

Importantly, the comprehension of different cellular and molecular mechanisms by which common classes of chemotherapy and targeted therapy drugs induce cardiotoxic effects is critical for developing efficient strategies for prevention, early detection, and treatment. Several therapeutical approaches have already been proposed to cope with the cardiotoxic side effects of anticancer therapies, including iron-chelating drugs,  $\beta$ -blockers, renin-angiotensin-aldosterone system inhibitors, sodium-glucose cotransporter-2 (SGLT2) inhibitors, late inward sodium current (INaL) selective inhibitors, phosphodiesterase-5 inhibitors, metabolic agents, statins, and growth factors. As future therapeutic goal, moving toward a protective chemoprevention approach, we need well-tolerated drugs that may flank chemotherapy to reduce clinical and subclinical cardiotoxic side effects, without interfering with the action of the antineoplastic treatments (17).

## CARDIOTOXICITY MECHANISMS ASSOCIATED WITH COMMON CLASSES OF CHEMOTHERAPY DRUGS AND TARGETED THERAPY

### Chemotherapy Drugs

#### Anthracyclines

The anthracyclines, such as doxorubicin, daunorubicin, and epirubicin, are a class of broad-spectrum anticancer drugs extracted from *Streptomyces* bacterium. These compounds are used to treat different adult and pediatric hematologic cancers, such as leukemia and lymphomas, as well as many solid tumors, including breast, stomach, uterine, ovarian, bladder and lung cancers. However, anthracyclines are associated with a dose-dependent risk of cardiomyopathy and HF [reviewed in (2–7)]. Specifically, in the absence of risk factors, **doxorubicin** is tolerated up to a cumulative dose of 300 mg/m<sup>2</sup>, with a rate of HF of less than 2% (18). Retrospective studies have shown that an estimated 3–5% of patients, without other risk factors, would experience doxorubicin-related HF at a cumulative dose of 400 mg/m<sup>2</sup>, increasing at 7–26% and 18–48% for a dose of 550 and 700 mg/m<sup>2</sup>, respectively (18, 19). Based on these evident cardiotoxic effects, high-dose treatments with anthracycline are no longer administrated, but sub-acute and chronic cardiac effects are still a clinical problem. The use of second-generation analogs of doxorubicin, namely **epirubicin or idarubicin**, exhibits improvements in their therapeutic index, but the risks of inducing cardiomyopathy are not abated [reviewed in (6)]. Mitoxantrone, which is an anthracenedione, an anthracycline analog, can also damage the cardiac muscle cells, thus resulting in cardiac dysfunction (20) [reviewed in (21, 22)].

Importantly, a large body of evidence indicates that cardiomyopathy develops at lower doses of anthracyclines in the presence of risk factors, including hypertension, arrhythmias,

**TABLE 1 |** Main features and mechanisms of cardiotoxic side effect of chemotherapies and targeted therapies along with mitigating strategies.

Anti-cancer agent	Epidemiology of the cardiotoxicity	Cardiotoxic effect	Cellular and molecular mechanisms of cardiotoxicity	Mitigating strategies
<b>Anthracyclines</b> (e.g., doxorubicin, daunorubicin, epirubicin, idarubicin) <b>and anthracycline analogs</b> (e.g., mitoxantrone)	Patients without risk factors: <2% of doxorubicin-related heart failure for a cumulative dose of 300 mg/m <sup>2</sup> ; 3–5% for a cumulative dose of 400 mg/m <sup>2</sup> ; 7–26% for a dose of 550 mg/m <sup>2</sup> ; 18–48% for a dose of 700 mg/m <sup>2</sup> (18, 19). In patients with risk factors cardiomyopathy may occur at low doses of anthracyclines [reviewed in (23, 24)].	Permanent damage due to <u>cardiomyocyte</u> death [reviewed in (34)].  Maladaptive effects on <u>fibroblasts</u> , <u>endothelial cells</u> , <u>vascular smooth muscle cells</u> and <u>immune cells</u> , leading to pathological left ventricular remodeling [reviewed in (67)].	Mitochondrial dysfunction in <u>cardiomyocytes</u> induced by formation of reactive oxygen species (ROS), iron-catalyzed formation of free radicals, lipid peroxidation, and cardiolipin sequestration (44, 45) [reviewed in (6, 14, 34, 38)]. Alteration of mitochondria structural integrity in <u>cardiomyocytes</u> (55). DNA double-strand breaks (DSBs) in <u>cardiomyocytes</u> induced by topoisomerase 2 (Top2) (45, 56) [reviewed in (4, 6)].  Increased transforming growth factor beta (TGF-β) signaling and <u>myofibroblasts</u> activation [reviewed in (67)]. Increased <u>endothelial cell</u> permeability [reviewed in (67)]. Activation of <u>immune cells</u> [reviewed in (67)].  Protein kinase C-mediated vasoconstriction in <u>vascular smooth muscle cells</u> (78) [reviewed in (69)]. Reduced oxygen transport capacity of <u>erythrocytes</u> , inducing relative ischemia of the myocardium (79). Increased ROS production in <u>endothelial cells</u> , leading to cell senescence and death, in turn triggering a procoagulant state (77) [reviewed in (69)]. ROS production and induction of <u>cardiomyocyte</u> apoptosis and autophagy (77).	<b>Iron-chelating drug:</b> dexrazoxane (56, 202, 203, 206) [reviewed in (14, 204, 207)]. <b>β-Blockers</b> [reviewed in (16, 37)]: metoprolol (216, 217) carvedilol (220–226) nebivolol (228, 230, 231). <b>RAAS inhibitors:</b> ACE-Is such as enalapril, captopril, lisinopril, and ramipril (235–237, 239–241), ARBs such as candesartan and telmisartan (216, 242–245), aldosterone antagonists (251). <b>Combination of RAAS inhibitors and β-blockers</b> (33, 247). <b>SGLT2 selective inhibitors:</b> empagliflozin (256–259). <b>INaL inhibitor:</b> ranolazine (261, 262, 264). <b>Phosphodiesterase-5 inhibitors:</b> sildenafil, tadalafil (267–269). <b>Metabolic agents:</b> butyric acid (273), β-hydroxybutyrate (276). <b>Statins</b> (279–282). <b>Growth factors:</b> neuregulins (134, 284, 285, 287), G-CSF (289), erythropoietin (290). <b>PPARα activators:</b> fenofibrate (292). <b>Remote ischemic preconditioning</b> (293).  <b>β-Blockers</b> , together with <b>calcium channel blockers</b> , <b>nitrates</b> , and <b>aspirin</b> [reviewed in (68, 71, 213)].
<b>Fluoropyrimidines</b> (e.g., 5-fluorouracil, capecitabine)	1–19% cardiotoxic events [reviewed in (69, 73, 75)].	Generally reversible coronary artery spasm, although <u>cardiomyocyte</u> death and loss may occur as consequence of coronary artery thrombosis and myocardial infarction [reviewed in (69, 75, 76)], as well as directly through cardiomyocyte-intrinsic mechanisms (77).		

(Continued)

TABLE 1 | (Continued)

Anti-cancer agent	Epidemiology of the cardiotoxicity	Cardiotoxic effect	Cellular and molecular mechanisms of cardiotoxicity	Mitigating strategies
<b>Taxanes</b> (e.g., paclitaxel)	3–20% cardiotoxic events (81, 82) [reviewed in (84)].	Mild, primarily QT interval prolongation, followed by bradycardia and atrial fibrillation (82).	Hypersensitivity reaction with massive histamine release with consequent disturbance of the <u>conduction system</u> and arrhythmia (82). Increased ROS production by <u>cardiomyocyte</u> mitochondria, collapse of mitochondrial membrane potential and opening of mitochondrial permeability transition pore (91). Pharmacokinetic interference of doxorubicin elimination by paclitaxel [reviewed in (94)].	<b>Anti-inflammatory:</b> glucocorticoids [reviewed in (37, 88, 90)]. <b>Anti-histamine drugs:</b> histamine receptor blockers [reviewed in (37, 88, 90)].
<b>Alkylating drugs</b> (e.g., cisplatin, cyclophosphamide, ifosfamide, mitomycin)	7–32% of patients (96) [reviewed in (97)].	Permanent damage due to thromboembolic events and vascular damage, in turn inducing <u>cardiomyocyte</u> degeneration and necrosis (99) [reviewed in (87)].  Pro-inflammatory effects leading to pathological left ventricular remodeling (101).	Increased <u>platelet</u> reactivity by activation of arachidonic pathway [reviewed in (87)]. Oxidative stress and direct <u>endothelial</u> capillary damage with resultant extravasation of proteins, <u>erythrocytes</u> , and toxic metabolites, in turn causing a damage to the myocardium [reviewed in (99)]. Expression of proinflammatory chemokines and cytokines driven by increased NFkB activation (101, 102).	<b>Amino acids:</b> taurine (102). <b>NADPH oxidase inhibitors:</b> apocynin (101).
<b>ERBB targeting monoclonal antibodies</b> (e.g., trastuzumab, pertuzumab) <b>and tyrosine kinase inhibitors</b> (e.g., lapatinib, tucatinib)	Cardiotoxicity in 2–5% of <b>trastuzumab</b> -treated patients, leading to heart failure in 1–4% of the cases (151–153) [reviewed in (155, 156)]. Limited data regarding the sole <b>pertuzumab</b> cardiotoxicity [reviewed in (37, 297)]. The risk of heart failure is increased by the addition of pertuzumab to trastuzumab plus chemotherapy regimes (171). 2–5% LVEF reduction in patients treated with <b>lapatinib</b> , and in 1% of patients treated with tucatinib [reviewed in (173)]. Combination of lapatinib with trastuzumab does not increase cardiotoxicity (175).	Generally reversible alteration of <u>cardiomyocyte</u> contractile function {trastuzumab [reviewed in (8, 158)] and pertuzumab [reviewed in (174)]}.	Inhibition of the signaling activated by Neuregulin-1 (NRG1), a paracrine growth factor released by cardiac <u>endothelial cells</u> [reviewed in (110–112)].	<b>β-Blockers:</b> bisoprolol (215). <b>RAAS inhibitors:</b> ACE-Is such as perindopril (215). <b>Combination of RAAS inhibitors (ACE-Is) and β-blockers</b> (248, 249). <b>INaL inhibitor:</b> ranolazine (265, 266). <b>Statins</b> (283).

(Continued)

TABLE 1 | (Continued)

Anti-cancer agent	Epidemiology of the cardiotoxicity	Cardiotoxic effect	Cellular and molecular mechanisms of cardiotoxicity	Mitigating strategies
<b>VEGFR/PDGFR tyrosine kinase inhibitors</b> (e.g., sunitinib, sorafenib)	May exacerbate anthracycline-induced toxicity, reaching 28% of heart failure incidence when <b>trastuzumab</b> is <b>combined with anthracyclines</b> (165). Up to 47% of patients receiving sunitinib treatment experienced hypertension, up to 28% showed LV dysfunction, and 8% developed congestive heart failure [reviewed in (15)].	Exacerbation of anthracycline-induced permanent damage through increased <u>cardiomyocyte</u> death (140).  Generally reversible [reviewed in (37, 76, 193)].	Increase in anthracycline-induced ROS accumulation and consequent <u>cardiomyocyte</u> death (167).  Sunitinib- or sorafenib-induced VEGFR inhibition reduces the production of the vasorelaxant nitric oxide (NO) by endothelial cells, in turn resulting in hypertension. In turn, hypertension may lead to capillary rarefaction, which may cause LV dysfunction [reviewed in (15, 194)]. Sunitinib- or sorafenib-induced VEGFR inhibition reduces angiogenesis resulting in LV dysfunction [reviewed in (15, 194)]. Sunitinib- or sorafenib-induced PDGFR inhibition induces the loss of <u>pericytes</u> , leading to coronary microvascular dysfunction and LV dysfunction [reviewed in (15, 194)].  Ponatinib-induced cardiotoxic effects were suggested to be consequent to thrombotic microangiopathy and consequent ischemia (199).	<b><math>\beta</math>-Blockers</b> (214): bisoprolol (216), carvedilol (226). <b>RAAS inhibitors:</b> ACE-Is such as lisinopril (226). <b>Statins</b> (283).  <b>SGLT2 selective inhibitors:</b> empagliflozin (260).  <b>Growth factors:</b> neuregulins [proof-of-principle study in (200), reviewed in (197)].
<b>BCL-ABL tyrosine kinase inhibitors</b> (e.g., imatinib, ponatinib)	Despite initial fears (196), the rate of cardiotoxicity upon imatinib treatment was shown to be extremely low, with less than 1% of the patients developing heart failure [reviewed in (37, 197)]. More than 20% of patients receiving ponatinib treatment experienced adverse cardiovascular event, 5% developed congestive heart failure [reviewed in (181, 197)].	Generally reversible (181).		

coronary disease, combination with other anticancer agents as well as genetic predisposition to cardiotoxicity [reviewed in (17, 23, 24)]. In this regard, among the genetic factors increasing the susceptibility to anthracycline-induced cardiotoxic effects, the role of specific single-nucleotide polymorphisms (SNPs) is emerging [reviewed in (24, 25)]. Indeed, heritability analysis on multiple cell lines unveiled SNPs from 30 genes giving a greater predisposition to daunorubicin-induced cardiotoxicity (26). Specifically, several SNPs associated with anthracycline cardiotoxicity affect genes involved in anthracycline metabolism, transport, or downstream cytotoxic effects. For example, studies on pediatric cohorts enlightened polymorphisms in CBR1 and CBR3 genes (encoding for carbonyl reductases) associated with enhanced cardiotoxicity susceptibility in children with cancer (27), polymorphisms in ABCC1 and ABCC5 genes (encoding for ATP-binding cassette transporters) associated with increased anthracycline-induced cardiac dysfunction in acute lymphoblastic leukemia patients (28, 29), polymorphisms in SLC22A gene (encoding for a solute carrier) (30), as well as polymorphisms in genes playing a role in iron homeostasis (31), and others [reviewed in (25, 32)]. Oppositely, SNPs in endothelial nitric oxide synthase (NOS3) gene have been reported to be cardioprotective in patients upon a high dose of doxorubicin (29).

Cardiac injury after anthracycline administration occurs with every dose, as documented by the analysis of cardiac-biopsy specimens a few hours after a single dose of anthracycline [reviewed in (7)]. Although the vast majority (98%) of cases of anthracycline cardiotoxicity being detected within the first year after completing the treatment (33), anthracycline-induced cardiotoxicity can also manifest months to years after completing chemotherapy (33). From a pathophysiological point of view, anthracyclines were suggested to induce cardiotoxicity through cardiomyocyte-intrinsic mechanisms as well as other mechanisms involving other cardiac cell types (**Figure 1**). Importantly, anthracycline-induced cardiac damage may be permanent due to cardiomyocyte death through several biological processes, including apoptosis, autophagy, necrosis, necroptosis, pyroptosis, and ferroptosis [reviewed in (34)]. In this regard, the alteration of mitochondrial function and integrity emerged as a distinctive feature of anthracycline-induced cardiomyopathy [reviewed in (7, 34–39)]. Mitochondria network is well developed in the cardiac muscle, occupying 36–40% of the cardiomyocyte volume and producing around 90% of the cellular energy [reviewed in (40–43)]. Among the complex underlying molecular mechanisms involved in anthracycline-induced mitochondrial dysfunction is worth to mention the formation of reactive oxygen species (ROS), iron-catalyzed formation of free radicals, lipid peroxidation, and cardiolipin sequestering (44, 45) [reviewed in (6, 14, 34, 38)]. In this regard, in cardiac mitochondria, anthracyclines can be reduced by NAD(P)H-oxidoreductases and converted to unstable metabolites, such as doxorubicin-semiquinone radicals, which can react with molecular oxygen ( $O_2$ ), producing superoxide anion-free radicals and hydrogen peroxide ( $O_2^-$  and  $H_2O_2$ ) (46) [reviewed in (37)]. ROS generated by anthracyclines affect the activity of many mitochondrial enzyme complexes, such as NOSs,

NAD(P)H oxidases, catalase, and glutathione peroxidase (GPx), leading to DNA, protein, and lipid damage, and consequently to cardiomyocyte death [reviewed in (39, 47, 48)]. Moreover, anthracyclines, such as doxorubicin, have been reported to impair cardiac iron homeostasis, resulting in its overload in the cardiac tissue [reviewed in (14, 49, 50)]. Accordingly, patients with anthracycline-induced cardiac dysfunction exhibit higher iron levels in cardiac mitochondria, compared to healthy individuals or patients suffering from anthracycline-independent cardiac dysfunction (44). Doxorubicin can, in fact, chelate the free intracellular iron and form iron-doxorubicin complexes, which, in turn, are able to react with  $O_2$ , further increasing the generation of ROS [reviewed in (4, 14, 49, 50)]. In addition, anthracyclines can directly interfere with the main iron-transporting/-binding proteins. For example, doxorubicin can impair cellular iron mobilization, resulting in its accumulation within ferritin (51), and can reduce the expression of the mitochondrial iron exporter ABCB8 (44). Recent studies have also focused on the detrimental role of mitochondrial iron-doxorubicin complexes triggering cardiomyocyte ferroptosis, a kind of programmed cell death dependent on iron and induced by lethal lipid peroxidation (52) [reviewed in (50)]. In this regard, doxorubicin-induced cardiotoxicity in mouse models was shown to be consequent to a decrease in the expression levels of glutathione peroxidase 4 (GPx4), which is a scavenger for lipid peroxides, in turn inducing peroxidation of unsaturated fatty acids and lipids (52). Anthracyclines are also linked to mitochondria damage because of their high affinity to cardiolipin, a mitochondrial membrane phospholipid that is involved in apoptotic pathways [reviewed in (35, 53)]. Mechanistically, doxorubicin sequesters cardiolipin avoiding its anchorage to cytochrome C or lipid-protein interfaces, thus contributing to mitochondrial dysfunction and ROS formation (54) [reviewed in (35, 53)]. Along with the impaired cardiac mitochondrial function, anthracyclines have been demonstrated to alter the structural integrity of mitochondria. Indeed, it has been reported that doxorubicin stimulates the receptor-interacting protein 3 (RIPK3)-induced activation of  $Ca^{2+}$ -calmodulin-dependent protein kinase (CaMKII), thus triggering the opening of mitochondrial permeability transition pore (MPTP), and ultimately inducing necroptotic cardiomyocyte death (55).

Several lines of evidence have suggested that nuclear damage induced by topoisomerase 2 (Top2) is another pivotal event in anthracyclines' cardiotoxic effects (45, 56) [reviewed in (4, 6)]. Specifically, doxorubicin intercalates into DNA and interacts with both Top2-alpha (Top2 $\alpha$ ) and Top2-beta (Top2 $\beta$ ), which are enzymes responsible for managing DNA tangles and supercoils. Top2 $\alpha$  is highly expressed in proliferating cancerous cells but not in quiescent tissues; therefore, it is considered one of the key molecular targets of anthracycline anti-tumoral effect (56). Cardiomyocyte toxicity stems from the fact that doxorubicin interacts with cardiac Top2- $\beta$ , the only isoform expressed by adult mammalian cardiomyocytes. Consequently, the Top2 $\beta$ -doxorubicin-DNA complex induces DNA double-strand breaks (DSBs), ultimately promoting cardiomyocyte death (45, 56).

Tumor protein P53 (p53) has also been implicated in anthracyclines' cardiotoxic response, although its involvement is currently controversial. Indeed, it has been reported that DNA breaks, induced by acute doxorubicin administration, lead to activation of the DNA damage response (DDR) network, in turn activating p53, which ultimately promotes the apoptotic cascade (57) [reviewed in (58)]. Moreover, in response to cell stress, p53 was shown to accumulate in the cytosol and to localize in mitochondria, triggering a series of death-events related to mitochondrial dysfunction, such as the permeabilization of the mitochondrial outer membrane (MOMP), the release of cytochrome C, the opening of the mitochondrial permeability transition pore (PTP), the impairment of mitochondria, and the production of ROS (59–63). Mice depleted for p53 exhibit a less impaired mitochondrial integrity and reduced cardiac dysfunction following doxorubicin treatment [reviewed in (5)]. In addition, doxorubicin-activated p53 has been shown to contribute to metabolic derangement by inhibiting mitophagy events (45) [reviewed in (4)]. As a result of cytosolic accumulation, p53 binds Parkin and abrogates its translocation to damaged mitochondria and their subsequent clearance by mitophagy (64) [reviewed in (5)]. These results support p53 as a key player in anthracycline-related cardiomyopathies (61, 62) [reviewed in (4)]. Nevertheless, other studies unveiled opposite effects depending on the dosage and timing of doxorubicin-induced cellular stress. Indeed, upon low doses of doxorubicin, which more closely recapitulate the clinical settings, it has been reported a protective role of p53, counteracting the late-onset cardiomyopathy and without activation of p53-dependent cell death cascades (65, 66).

In addition to cardiomyocyte-intrinsic mechanisms, anthracyclines exhibit a wide range of maladaptive effects on other cardiac populations, including fibroblasts, endothelial cells, vascular smooth muscle cells, and immune cells [reviewed in (67)]. In particular, doxorubicin administration was shown

to increase endothelial cellular permeability, in turn causing edema formation [reviewed in (67)], to induce ROS-dependent activation of transforming growth factor beta (TGFβ) signaling, in turn triggering myofibroblast activation and collagen deposition [reviewed in (67)], and to induce the activation of the innate immune system and inflammatory response [reviewed in (67)]. Overall, these events were suggested to lead to pathological left ventricular remodeling [reviewed in (67)].

### Fluoropyrimidines

Fluoropyrimidines exert the second most common cause of chemotherapy-induced cardiotoxicity [reviewed in (68–74)]. This antimetabolite drug class, which includes **5-fluorouracil (5-FU)** and its prodrug **capecitabine**, is incorporated into DNA or RNA, thus acting as cytostatic agent for the clinical treatment of colorectal, breast, gastric, pancreatic, prostate, and bladder cancers [reviewed in (74)]. Fluoropyrimidines are generally well tolerated; nevertheless, 1–18% of the patients receiving fluoropyrimidines experiences cardiovascular toxicity [reviewed in (69–71, 73–75)]. Cardiovascular side effects associated with fluoropyrimidines include a generally reversible coronary artery spasm and myocardial ischemia, although cardiomyocyte death and loss may occur as consequence of coronary artery thrombosis and myocardial infarction [reviewed in (69, 75, 76)], as well as directly through cardiomyocyte-intrinsic mechanisms (77). These adverse effects were suggested to be mediated by vascular smooth muscle cells, erythrocytes, endothelial cells as well as directly by cardiomyocytes (**Figure 2**). From a molecular point of view, 5-FU was reported to induce protein kinase C-mediated vasoconstriction in vascular smooth muscle cells (78) [reviewed in (69)]. 5-FU was also shown to reduce the oxygen transport capacity of erythrocytes, inducing relative ischemia of the myocardium (79). 5-FU administration was also suggested to induce increased ROS production in endothelial cells, leading to cell senescence and death (77), in turn

triggering a procoagulant state and acute thrombotic events [reviewed in (69)]. Finally, direct cardiomyocyte toxicity after fluoropyrimidine administration has also been suggested. Indeed, 5-FU has also been demonstrated to favor ROS production and to induce cardiomyocyte apoptosis and autophagy (77).

## Taxanes

Taxanes, such as **paclitaxel**, are antimitotic agents that stabilize microtubules in the mitotic spindle, thus blocking cell cycle progression. These chemotherapy drugs are widely employed in cancer treatment, including breast, lung, and ovarian cancers. However, significant toxicities limit the effectiveness of taxane-based treatment regimens (80). Taxane administration is reported to induce cardiotoxic events in 3–20% of the patients (81, 82) [reviewed in (83–85)]. Taxane-induced cardiotoxic effects include QT interval prolongation, followed by bradycardia and atrial fibrillation (82). Because taxane-induced cardiotoxicity appears to be mild in most cases and reversible upon discontinuation of the therapy, no specific agents are recommended for their management [reviewed in (86, 87)].

The underlying cellular and molecular mechanisms of taxane-induced cardiotoxicity are unclear; however, a few hypotheses have been proposed (Figure 3). Among them, hypersensitivity reaction with a massive histamine release and consequent disturbance of the conduction system and arrhythmia has been proposed (82). Hence, the administration of anti-inflammatory (glucocorticoids) and anti-histamine drugs (histamine receptor blockers), is suggested as prophylactic therapy for the management of cardiac anaphylaxis induced by taxanes [reviewed in (37, 88–90)]. Another hypothesis is cardiomyocyte damage through the drug's actions on subcellular organelles (82). In this regard, taxanes were suggested to increase ROS production by cardiomyocyte mitochondria, the opening of mitochondrial permeability transition pore and the collapse of mitochondrial membrane potential (91).

Among taxanes, paclitaxel has been shown to exacerbate anthracycline-induced toxicity. Indeed, combined treatment with paclitaxel and doxorubicin augmented HF events (92) and increased histopathological alterations of cardiac tissue, with extensive necrosis (93). This effect was suggested to derive from a pharmacokinetic interference of doxorubicin elimination by paclitaxel [reviewed in (94)]. No interaction between doxorubicin and other taxanes (such as docetaxel) has been reported; in line, **docetaxel** showed no increase in cardiac toxicity when combined with doxorubicin [reviewed in (94)].

## Alkylating Drugs

Alkylating drugs, such as cisplatin, cyclophosphamide, ifosfamide, mitomycin, are crosslinking agents inducing ROS production, DNA damage and apoptosis in cancer cells [reviewed in (95)]. **Cisplatin** is mostly used in combination with other chemotherapy drugs to overcome drug-resistance and reduce toxicity [reviewed in (95)]. Cisplatin-based chemotherapy has been reported to cause cardiovascular diseases, particularly myocardial infarction and angina, in a range of 7–32% of patients (96) [reviewed in (97)]. In patients treated with cisplatin, a long-term unfavorable cardiovascular risk profile was observed,

with hypercholesterolemia, hypertriglyceridemia, hypertension and insulin-resistance evaluated after more than 10 years from remission (98). The cardiotoxic effects of alkylating agents may be permanent and a few cellular and molecular mechanisms were suggested to contribute to these processes (Figure 4). Indeed, cisplatin administration has been linked with thromboembolic events associated with platelet aggregation and vascular damage (99) [reviewed in (87)], in turn resulting in cardiomyocyte degeneration and necrosis. The increased platelet aggregation was suggested as a direct consequence of cisplatin on the activation of the arachidonic pathway in platelets [reviewed in (87)]. The endothelial capillary damage was suggested to derive from a cisplatin-dependent increase in oxidative stress (99). Indeed, cisplatin has also been shown to induce oxidative stress in myocardial tissue, with decreased activity of glutathione and antioxidant enzymes (100, 101). The consequence of cisplatin-induced endothelial injury was suggested to be the extravasation of proteins, erythrocytes, and toxic metabolites, in turn causing damage to the myocardium (99). Finally, cisplatin has also been suggested to activate NF- $\kappa$ B in the cardiac tissue (101), in turn increasing the expression of proinflammatory chemokines and cytokines (102). This mechanism was proposed to result in cardiac remodeling (101), and extensive degeneration and fragmentation of cardiac muscle fibers (102).

The alkylating agent **cyclophosphamide** at high doses can cause hemorrhagic cell necrosis and may lead to HF; however, with the lower doses currently used, these side effects are infrequent (103).

## Targeted Therapy

### ERBB Targeted Therapies

Growth factor receptors of the ERBB family (EGFR/ERBB1, ERBB2, ERBB3, and ERBB4) play a key role in the development and progression of a variety of solid cancers [reviewed in (104–106)]. After the binding of soluble ligands, ERBB kinase receptors arrange in homo- or heterodimer complexes, which activate the tyrosine kinase activity and the consequent signaling events leading to the modulation of cell survival, proliferation, migration, and differentiation [reviewed in (104–107)]. ERBB2 (also known as HER2) receptor is a proto-oncogene frequently amplified and overexpressed in many human cancers. Unlike the other ERBB receptors, ERBB2 is unable to bind ligands but heterodimerizes with other ERBB receptors, stabilizing the ligand interaction with the coupled receptors, enhancing and diversifying the ligand-induced receptor signaling (108) [reviewed in (107)]. Several strategies have been developed to target the key role of ERBB2 signaling in tumor development and progression. Successful approaches are represented by treatment with humanized ERBB2-targeting antibodies (e.g., trastuzumab and pertuzumab) and tyrosine kinase multi-HER inhibitors (e.g., lapatinib, tucatinib, afatinib, neratinib, and dacomitinib), which effectively showed ERBB2 inhibition and tumor regression, particularly in the treatment of mammary carcinomas [reviewed in (109)].

The cardiotoxicity of ERBB2-directed therapeutics is consequent to the inhibition of the signaling activated by

Neuregulin-1 (NRG1), a paracrine growth factor released by cardiac endothelial cells featuring pivotal functions in the heart (**Figure 5**) [reviewed in (110–112)]. NRG1, together with its tyrosine kinase receptors ERBB4, ERBB3, and ERBB2, is essential for heart development (113–115) [reviewed in (110, 116, 117)] and tunes heart regenerative, inflammatory, fibrotic, and metabolic processes (118, 119) [reviewed in (110, 117, 120–122)]. In cardiomyocytes, the most prominently expressed NRG1 receptors are ERBB4 and ERBB2 (123) and NRG1 stimulates fetal/neonatal cardiomyocyte proliferation, hypertrophy, sarcomerogenesis, and survival (114, 115, 124–127) [reviewed in (110, 116, 117, 120, 121)]. ERBB2 forms heterodimers with ERBB4 and is necessary for NRG1-elicited cardiomyocyte proliferation during embryonic and neonatal stages (122, 124). However, cardiac ERBB2 expression levels decline soon after birth in mice, as part of the mechanism leading to cardiomyocyte terminal differentiation, cell cycle withdrawal and loss of cardiac regenerative ability (124) [reviewed in (122)].

Despite low levels described in adulthood, ERBB2 appears to play a role in the prevention of dilated cardiomyopathy. Indeed, mice with ventricular-restricted deletion of ERBB2 exhibited multiple independent parameters of dilated cardiomyopathy, such as chamber dilatation, wall thinning, and decreased contractility (128). Decreased NRG1 signaling in postnatal life is associated with adverse cardiac function and susceptibility to stress [reviewed in (110, 116)]. The expression and activation of ERBB4 and ERBB2 receptors were found lower in myocardium from HF patients (129). In mice subjected to pressure overload, ERBB4 and ERBB2 undergo relevant reduction at mRNA and protein levels with the progression to HF (130).

Conversely, enhanced activity of NRG1 counteracts cardiac remodeling and HF progression [reviewed in (110, 116)]. Systemic administration of NRG1 improves cardiac function following various types of cardiac injuries in adult mice (115, 127, 131, 132) [reviewed in (110, 133)] and HF patients (117, 134–136) [reviewed in (137)].

Cardiac upregulation of ERBB2 was documented upon adverse hemodynamic or other stressful or toxic stimuli, including anthracycline therapies (138, 139). This increase is

required to sustain cardiomyocyte survival and cardiac function under stress conditions. Indeed, cardiomyocytes isolated from mice with ventricular-restricted deletion of ERBB2 were more susceptible to anthracycline toxicity, revealing a role for ERBB2 in cardiomyocyte survival upon chemotherapy administration (128). Conversely, cardiac-specific overexpression of ERBB2 in mice has been shown to decrease cardiomyocyte death upon doxorubicin administration (140).

EGFR (also known as ERBB1) is associated with cancer progression and its inhibition *via* monoclonal antibodies (such as cetuximab and panitumumab) or TKIs (such as erlotinib and gefitinib) has been the first strategy evaluated among growth factor receptors targeting therapies (141, 142). Nowadays, EGFR inhibitors are clinically used for the treatment of several solid cancers, including lung, head and neck, colorectal, and pancreatic cancers (142). Although cetuximab-associated cardiotoxicity has been reported in the clinical literature, the incidence of cardiac events in patients remains very low (143, 144).

### ERBB Targeting Monoclonal Antibodies

**Trastuzumab**, the first ERBB2-targeting humanized monoclonal antibody, binds the extracellular domain IV of ERBB2 receptor leading to the inhibition of ligand-independent heterodimerization between ERBB2 and other ERBB family members (145, 146) [reviewed in (105, 147)]. From a clinical perspective, the cardiotoxicity of monoclonal antibodies targeting ERBB2, such as trastuzumab, is moderate and reversible [reviewed in (148–150)]. Trastuzumab monotherapy is associated with cardiotoxicity in 2–5% of patients, leading to HF in 1–4% of the cases (151–153) [reviewed in (154–157)]. The mechanism of trastuzumab-induced cardiotoxicity appears to be the alteration of cardiomyocyte contractile function without cardiomyocyte death [reviewed in (8, 158)]. Interestingly, *ErbB2* gene polymorphisms that alter the ERBB2 protein sequence have been identified, and two of them (Ile 655 Val and Pro 1170 Ala) were associated with an increased risk of cardiotoxicity from trastuzumab therapy (32, 159–164). Importantly, with the concomitant association of trastuzumab and anthracyclines, HF incidence increased to 28% (165, 166).

Thus, trastuzumab-mediated blockade of ERBB2 signaling increases anthracycline-induced toxicity. The molecular mechanism underlying this combinatorial phenomenon may be due to the key role of ERBB2 in the management of oxidative stress in the heart: interrupting the neuregulin/ERBB2 axis, which is responsible for the activation of the glutathione reductase system, facilitates the anthracycline-induced accumulation of ROS and subsequent calcium influx, finally leading to caspase activation and cardiomyocyte death (167). Once anti-ERBB2 agents inhibit the ERBB2 protective mechanisms in cardiomyocytes, the doxorubicin oxidative damage was reported to increase (158) [reviewed in (37)].

**Pertuzumab**, a new generation of ERBB2-targeting therapies, is an antibody against domain II specifically designed to inhibit ligand-induced ERBB2 heterodimerization (168, 169). The data regarding the sole pertuzumab cardiotoxicity effects are still limited. Currently, combining trastuzumab/pertuzumab and trastuzumab/lapatinib, in order to induce a dual blockade of HER2, is part of the standard of care (170). In this regard, a recent study reporting a systematic review of eight randomized controlled trials showed that the risk of HF is increased by the addition of pertuzumab to trastuzumab plus chemotherapy therapeutic regimens (171).

### ERBB Kinase Inhibitors

Tyrosine kinase inhibitors selectively target and inhibit several oncogenic relevant receptor-tyrosine kinases (RTKs), inducing survival benefits in therapies for various hematological and solid cancers [reviewed in (172)]. TKIs include single-targeted and multi-targeted TKIs. A small group of small TKIs, including lapatinib (ERBB2 and EGFR inhibitor), tucatinib (ERBB2 inhibitor), erlotinib (EGFR inhibitor), gefitinib (EGFR inhibitor), afatinib (EGFR, ERBB2, and ERBB4 inhibitor), neratinib (EGFR, ERBB2, and ERBB4 inhibitor), and dacomitinib (EGFR, ERBB2, and ERBB4 inhibitor), has been developed to target ERBB receptors. However, these ERBB blockers can also exert cardiac toxicity in treated patients. In particular, about 2–5% of patients treated with lapatinib displayed a reduced LVEF, and similar effects were reported in 1% of patients treated with tucatinib [reviewed in (173)]. The decline in cardiac function is generally reversible [reviewed in (174)]. Regarding combinatorial anti-ERBB strategies, little is known about the cardiotoxic potential of ERBB2 double blockade with trastuzumab plus lapatinib. Although stronger inhibition of the HER2 pathway using two anti-HER2 drugs was initially expected to result in greater impairment of cardiomyocytes, preclinical tests suggested a possible cardioprotective mechanism exerted

by lapatinib. Adjuvant Lapatinib and/or Trastuzumab Treatment Optimisation (ALTTO), a randomized, multi-center, open-label, phase III study of adjuvant lapatinib plus trastuzumab treatment in patients with HER2/ERBB2 positive primary breast cancers (ClinicalTrials.gov, identifier NCT00490139), as well as other clinical trials with double ERBB2 blockade, support the safety of lapatinib plus trastuzumab treatment, since a lower, although not statistically significant, incidence of cardiac events was detected in patients in the trastuzumab plus lapatinib arm. This evidence does not imply that lapatinib has a cardioprotective effect, nor that it should be a preferred option for patients with an increased risk of cardiotoxicity (175).

Afatinib, an ERBB family blocker, approved for the first-line treatment of advanced non-small cell lung cancer (NSCLC) with EGFR mutations, is one of the few TKIs with a low risk of cardiotoxicity [reviewed in (176)]. Finally, cardiac side effects of the irreversible pan-ERBB inhibitor neratinib [reviewed in (177)] were reported neither in phase I clinical studies in solid tumors (178, 179) nor in a phase II trial in advanced HER2-positive breast cancer (179).

### Multi-Targeted Tyrosine Kinase Inhibitors

In addition to single- or multi-targeted ERBB family inhibitors (see the previous paragraph), other multi-targeted TKIs were developed to effectively block multiple pathways of intracellular signal transduction. The broad kinase-signaling inhibition of several TKIs, such as sunitinib, sorafenib, imatinib, and nilotinib, includes the vascular endothelial growth factor receptors (VEGFRs), platelet-derived growth factor receptors (PDGFRs), BCR-ABL, and c-KIT. This wide action results in a strong anti-malignancy effect of this class of drugs, although correlated with reversible myocardial dysfunctions with a wide range of severity (180) [reviewed in (37, 181–183)]. Clinical analysis of TKI anti-tumoral therapies shows that compounds with broader off-target effects as kinases inhibitors (lower selectivity in targeting a specific kinase) correlated to higher degree of cardiotoxicity, particularly in case the inhibited kinase plays a role in the maintenance of the cardiovascular system (184–186) [reviewed in (37)]. In this regard, sunitinib, which targets VEGFR/PDGFR and interferes with more than 30 tyrosine kinases; sorafenib, which targets VEGFR/PDGFR and inhibits at least 15 tyrosine kinases, including RAF/MEK/ERK pathway, and ponatinib, which targets BCR-ABL and several other RTKs, are responsible for major clinical concerns related to cardiotoxicity (172) [reviewed in (37, 187, 188)]. Of note, these three compounds (sunitinib, sorafenib, and sonatinib) target VEGF, PDGFR, and c-Kit, namely three tyrosine kinase receptors

involved in multiple key functions in the cardiovascular system, whose inhibition is likely the cause of the observed cardiotoxic effects (Figure 6). Particularly, **sunitinib**, which presents an effective multi-targeted inhibition of growth-factor receptors able to reduce the angiogenesis and tumor cell survival/proliferation (182, 189), is considered more cardiotoxic than other anti-angiogenic and TKI drugs (182). Based on clinical studies, 47% of patients receiving sunitinib treatment exhibited hypertension, up to 28% showed LV dysfunction, and 8% developed CHF [reviewed in (15)]. Patients with pre-existing cardiovascular diseases or previous cardio-toxicant exposure show even higher risks [reviewed in (190–192)]. However, cardiac dysfunctions induced by sunitinib and other inhibitors of tyrosine kinases have shown high reversibility; after treatment withdrawal, hypertension and cardiac dysfunction were alleviated or wholly restored (193) [reviewed in (37)]. Indeed, the majority of sunitinib-treated patients were able to carry on with sunitinib therapy following the resolution of cardiovascular events (193). Similarly, reversible cardiotoxicity has been reported upon sorafenib treatment [reviewed in (76)].

The cellular and molecular details of the observed elevated blood pressure and cardiac dysfunction in patients treated with anti-VEGF/PDGFR drugs, such as sunitinib and sorafenib, are not fully understood. Nevertheless, sunitinib- and sorafenib-induced VEGFR inhibition was suggested to reduce the production of the vasodilator nitric oxide (NO) by endothelial cells, in turn resulting in hypertension [reviewed in (15, 194)]. Hypertension is known to lead to capillary rarefaction, which may be responsible for the cardiac dysfunction observed in sunitinib and sorafenib-treated patients [reviewed in (15)]. Indeed, given the high energy dependency, the heart is usually highly vulnerable to any altered blood supply. However, the capillary rarefaction potentially responsible for cardiac dysfunction may also be a direct consequence of reduced angiogenesis following sunitinib- or sorafenib-induced VEGFR inhibition [reviewed in (15, 194)]. Further, sunitinib- or sorafenib-induced PDGFR inhibition was suggested to induce the loss of pericytes, in turn leading to coronary microvascular dysfunction (195) [reviewed in (15, 194)]. Sunitinib, as an off-target effect, has also been suggested to inhibit AMPK activity, in turn inducing energy depletion in cardiomyocytes (184). However, another study found that sunitinib treatment in cardiomyocytes does not affect cellular ATP levels and that

myocytes are not protected from sunitinib by pre-treatment with AMPK-activating drug metformin (189).

**Imatinib**, a TKI that inhibits BCR-ABL fusion protein, c-KIT, and PDGFR, is used to treat chronic myeloid leukemia and gastrointestinal stromal cancers. Despite initial fears (196), the rate of cardiotoxicity upon imatinib treatment was shown to be very low, with less than 1% of the patients developing HF [reviewed in (37, 197)]. Nevertheless, the inhibition of CaMKII in adult rat cardiac fibroblasts was shown to reduce the production of mitochondrial superoxide triggered by sunitinib and imatinib treatments (198).

Interestingly, **ponatinib**, a BCR-ABL kinase inhibitor developed to treat patients with imatinib resistance driven by T315I “gatekeeper” mutation, has been associated with a high rate of cardiovascular adverse events. Indeed, more than 20% of patients receiving ponatinib treatment experienced adverse cardiovascular events, and 5% developed CHF [reviewed in (181, 197)]. Of note, these cardiotoxic effects are often reversible with interruption of the therapy (181). The mechanisms of ponatinib-induced cardiotoxic effects are unclear; however, they were suggested to be consequent to thrombotic microangiopathy and consequent ischemia (Figure 6) (199), although cardiomyocyte death was also reported to occur in the zebrafish model (200).

## STRATEGIES TO REDUCE ANTICANCER DRUG-ASSOCIATED CARDIOVASCULAR TOXICITY

Several therapeutical approaches already known in clinical usage have been proposed to reduce cardiotoxicities, such as iron-chelating drugs,  $\beta$ -blockers, renin-angiotensin-aldosterone system (RAAS) inhibitors, SGLT2 inhibitors, late inward sodium current (INaL) selective inhibitors, phosphodiesterase-5 inhibitors, metabolic agents, statins as well as growth factors and hormones [previously reviewed in (201)]. Here we will discuss these classes of drugs, focusing on their mechanisms of action and the therapeutic validity and effectiveness.

### Iron-Chelating Drugs

The iron-chelating drug dexrazoxane has been identified as one of the most promising cardioprotective therapies in these last years and represents the only FDA-approved drug

**FIGURE 5 |** Cellular and molecular mechanisms of the cardiotoxic effect exerted by ERBB targeting monoclonal antibodies and tyrosine kinase inhibitors. Schematic diagram showing the impact of ERBB targeting therapies on cardiomyocyte dysfunction caused by the impairment of Neuregulin-1 signaling. However, in combination with anthracyclines, anti-HER2 monoclonal antibody trastuzumab may induce heart failure as a consequence of cardiomyocyte death induced by ROS accumulation.

**FIGURE 6 |** Cellular and molecular mechanisms of the cardiotoxic effects exerted by VEGFR/PDGFR and BCR-ABL and tyrosine kinase inhibitors. Schematic diagram showing the impact of VEGFR/PDGFR and BCR-ABL inhibition, resulting in a reversible cardiac dysfunction. Anti-VEGFR activity impairs cardiac function by inducing capillary rarefaction consequent to reduced angiogenesis or hypertension derived from reduced NO production. Anti-PDGFR activity induces cardiac dysfunction by promoting the loss of pericytes, which in turn impairs the coronary vasculature. Anti-BCR-ABL inhibition may result in myocardial ischemia and cardiac dysfunction consequent to thrombotic microangiopathy.

specific for anthracycline-induced cardiotoxicity (202, 203). Dexrazoxane is a pro-drug that rapidly turns into its active form after entering in cardiomyocytes, in turn counteracting the formation of anthracyclines-iron complexes and the subsequent adverse cardiac effects [reviewed in (204)]. Importantly, the development of iron-chelating drugs to prevent anthracycline-induced cardiotoxicity has emerged as an approach of relevant clinical importance in the context of the genetic predisposition of patients suffering from iron-related genetic disorders, such as hereditary hemochromatosis (31, 205). Initially, the cardioprotective functions of this iron chelator were ascribed majorly to its ability to affect iron regulatory proteins and reduce iron accumulation (206) [reviewed in (14, 207)]. However, additional mechanisms have been suggested to drive the cardioprotective activity exerted by dexrazoxane following anthracycline administration. Specifically, dexrazoxane has been shown to modify the topoisomerase 2 (Top2 $\beta$ ) configuration preventing its interface with anthracyclines, thereby avoiding the Top2-DNA cleavage complexes (56, 208). Close derivatives of dexrazoxane lacking the interaction with Top2 $\beta$  were found not to be protective in relevant chronic anthracycline cardiotoxicity models (206, 209). Thus, cardioprotective effects of dexrazoxane in chronic anthracycline cardiotoxicity were suggested to derive from the inhibition of the interaction between anthracyclines and Top2 $\beta$ , rather than to its metal-chelating action (209) [reviewed in (210)].

Recently, a study on the cardioprotective effects of dexrazoxane, based on seven randomized trials and two retrospective trials for a total of 2177 patients with breast cancer receiving anthracyclines with or without trastuzumab reported that dexrazoxane reduces the risk of clinical HF and cardiac events in these patients without significantly impacting cancer outcomes (203). Thus, dexrazoxane represents a therapeutical strategy to limit anthracycline cardiotoxicity.

## $\beta$ -Blockers

$\beta$ -blockers, also known as beta-adrenergic blocking agents, are a class of drugs that blocks the effects of the hormone epinephrine (adrenaline), causing the heart to beat more slowly and with less force, thus lowering blood pressure. These drugs are predominantly used to manage the reduction in left ventricular ejection fraction (LVEF), preventing symptomatic HF and protecting the heart from a second heart attack event after the first one (secondary prevention) [reviewed in (211, 212)]. The choice of  $\beta$ -blockers as a therapy for cardiac dysfunctions associated with anticancer drugs is mostly based on the dual cardioprotective role exerted by antihypertensive or antiarrhythmic drugs, which preserve cardiovascular function while inhibiting tumor angiogenesis [reviewed in (212)].  $\beta$ -blockers, together with calcium channel blockers, nitrates, and aspirin are recommended for the management of fluoropyrimidines-induced cardiotoxicity as

therapies for angina chest pain, albeit the absence of randomized controlled trials to support their efficacy [reviewed in (68, 71, 213)]. Furthermore, a large number of observations indicate  $\beta$ -adrenergic receptor signaling alterations as a feature of anthracycline-induced cardiomyopathy and in other forms of dilated cardiomyopathies [reviewed in (16, 37)]. A retrospective survey between 2005 and 2010 on 920 breast cancer patients who received anthracyclines and trastuzumab showed an association of continuous  $\beta$ -blocker treatment with a significantly lower incidence of HF events (214). **Bisoprolol**, another second-generation  $\beta$ -blocker, showed stronger efficacy compared to angiotensin-converting-enzyme inhibitor (ACE-I) **perindopril** in attenuating the LVEF decline in patients who received trastuzumab, even though it was unable to avoid left ventricular remodeling (215). However, administration of **metoprolol**, a second-generation  $\beta$ -blocker, did not affect LVEF decline determined by adjuvant, anthracycline-containing regimens with or without trastuzumab and radiation (216) and showed a non-statistically significant reduction in the incidence of anthracycline-induced HF events (217).

In *in vitro* and *ex vivo* set-up, **carvedilol**, a non-selective  $\beta$ - and  $\alpha$ 1-AR antagonist with strong antioxidant properties, reduced doxorubicin-induced ROS release and cardiomyocyte apoptosis (218) as well as mitochondrial respiration dysfunctions and calcium overloading (219). In rat models of doxorubicin-induced cardiomyopathy, carvedilol showed a significant cardioprotective effect, while **atenolol**, a  $\beta$ -blocker selective for  $\beta$ 1-AR and without antioxidant properties, did not, thus suggesting that carvedilol cardioprotective efficacy relies more on its antioxidant properties than on the  $\beta$ -AR blocking action (220). In clinical trials of patients undergoing anthracycline chemotherapy, the prophylactic use of carvedilol decreased the ventricular dysfunction (221–223). In children receiving anthracyclines for acute lymphocytic leukemia, pre-treatment with carvedilol reduced troponin, diastolic dysfunction, and lactate dehydrogenase levels (224, 225). Furthermore, a randomized trial on 468 breast cancer patients treated with anthracyclines with/without trastuzumab showed reduced cardiotoxicity upon carvedilol administration, hence recommending carvedilol as a strategy to reduce trastuzumab interruptions (226).

**Nebivolol** is a cardio-selective  $\beta$ -blocker with mild vasodilating effects due to its interaction with the arginine/NO pathway [reviewed in (227)]. In isolated perfused rat hearts model of anthracycline-induced cardiotoxicity, treatment with nebivolol increased NO levels and significantly reduced oxidative stress, and improved cardiac function (228). Mechanistically, experiments in the rat model suggested that nebivolol administration reduces alterations in cardiomyocyte histomorphometry induced by doxorubicin through modulation of caspase-3, NO synthase (NOS), and TNF- $\alpha$  (229). In randomized placebo-controlled studies, the prophylactic use of nebivolol preserved the cardiac diastolic and systolic function from anthracycline-induced toxicity (230, 231).

To date, the cardioprotective efficacy of  $\beta$ -blockers needs to be further validated in large clinical trials. In addition, in clinical practice, the usage of  $\beta$ -blockers is hampered by their adverse

effects in fragile patients, indicating their possible application only in patients with a high cardiotoxicity risk.

## Renin-Angiotensin-Aldosterone System Inhibitors

Several studies showed that alteration of the RAAS has a crucial role in modulating anthracycline-induced cardiotoxicity [reviewed in (232)]. Therefore, the development of RAAS inhibitors, including ACE-Is, angiotensin receptor type 1 blockers (ARBs), as well as aldosterone antagonists, may be effective in the prevention and treatment of anthracycline-induced cardiotoxicity [reviewed in (232, 233)].

**Angiotensin-converting-enzyme inhibitors**, such as enalapril, captopril, lisinopril, and ramipril, impair the conversion of angiotensin I to angiotensin II, with a consequent decrease of angiotensin II receptor type 1 (AT1R) stimulation and its downstream signaling. These compounds have been demonstrated effective in the treatment of hypertension, as well as in reducing mortality in left ventricular dysfunction after myocardial infarction and CHF (234). Preclinical studies in animal models have demonstrated that ACE-Is, such as enalapril, captopril, and lisinopril, can effectively counteract the cardiotoxic effects after single high-dose, multiple low-doses or chronic exposure of anthracyclines (235–238). Mechanistically, ACE-Is' therapy has been shown to result in the neutralization of ROS damage, reduction of interstitial fibrosis, limitation of intracellular calcium overload, along with improvement of mitochondrial respiration and cardiomyocyte metabolism (235, 236) [reviewed in (232)]. In retrospective clinical analysis, **enalapril** administration to doxorubicin-induced HF children increased cardiac hemodynamic parameters; however, these parameters declined after a few years (239). ACE-I therapy with **ramipril** or **enalapril** was also shown to induce the recovery of cardiac parameters in patients with doxorubicin-induced cardiac function decline (240). However, no significant improvement in exercise ability or contractile state of pediatric cancer patients receiving anthracyclines was also reported upon enalapril administration, albeit with reduction of left ventricular end-systolic wall stress (241). Clinical trials on HER2-positive breast cancer patients under anthracycline-trastuzumab therapy enlightened cardioprotective effects upon the administration of the ACE-I **lisinopril** (226).

Angiotensin receptor type 1 blockers, such as candesartan and telmisartan, inhibit angiotensin II binding to AT1R. In preclinical rat models, **candesartan** significantly reversed the daunorubicin-induced myocardial pathological changes and cardiac dysfunction (242). Candesartan administration was shown to significantly alleviate the decline in LVEF occurring during adjuvant, anthracycline-containing regimens with or without trastuzumab and radiation (216). Furthermore, in a small prospective study of 49 patients free from cardiovascular diseases and affected by solid cancers, **telmisartan** treatment starting before chemotherapy was able to reduce epirubicin-induced ROS damage by antagonizing the pro-inflammatory signals and reversing the early myocardial impairment (243). Telmisartan administration was also associated with long-lasting

(up to 18 months) protection from early and acute myocardial dysfunction in patients treated with epirubicin (244, 245). In contrast, the administration of candesartan was unable to protect against the decrease in left ventricular ejection fraction during or shortly after trastuzumab treatment (246).

Importantly, clinical trials have also shown that a combination of ACE-Is or ARBs and  $\beta$ -blockers has beneficial effects in treating cardiotoxicity induced by anthracyclines and/or anti-HER2 agents. Indeed, the combination of ACE-Is (enalapril) and  $\beta$ -blockers significantly reduced the incidence of cardiac dysfunction along with prevention of the onset of late cardiotoxicity in patients receiving anthracyclines (33, 247). A small phase I trial conducted on 20 women suffering from breast cancer assessed the safety of continuing trastuzumab treatment despite cardiotoxicity onset if patients received ACE-Is and  $\beta$ -blockers following a staggered protocol (248). Another study unveiled the combination of ACE-Is,  $\beta$ -blockers and close cardiac monitoring as an effective strategy for cardioprotection in patients receiving HER2-targeted therapies (249).

Further studies focused on the cardioprotective role of **aldosterone antagonists**, which inhibit the last step of the RAAS and are already known for their beneficial effects on injury-induced cardiac remodeling and fibrosis [reviewed in (250)]. In a small clinical trial, spironolactone has been reported to prevent anthracycline-related cardiac dysfunction in breast cancer patients (251).

## Sodium-Glucose Cotransporter-2 Inhibitors

Sodium-glucose cotransporter-2 selective inhibitors (empagliflozin, canagliflozin, and dapagliflozin) are a group of compounds that have been shown to have protective effects on the progression of HF [reviewed in (252)]. Indeed, EMPA-REG OUTCOME trial demonstrated that empagliflozin reduces major adverse cardiovascular events, cardiovascular death, and hospitalization rates for HF (253). Similarly, EMPEROR-Preserved trials found a reduced risk of HF hospitalization for 9718 patients with HF treated with empagliflozin (254). In a new systematic review meta-analysis of seven studies, for a total of 5,150 HF patients, empagliflozin was effective in reducing cardiovascular death or hospitalization for worsening HF condition (255). Therefore, SGLT2 inhibitors represent a promising treatment for chronic HF patients.

Recently, the potentially protective effects of SGLT2 inhibitors on the cardiac dysfunction induced by chemotherapies and targeted therapies were also investigated in preclinical studies in animal models. In this regard, protective effect by empagliflozin against anthracycline-induced cardiac impairment, diastolic dysfunction, and maladaptive cardiac remodeling has been documented (256–259). Mechanistically, empagliflozin was suggested to reduce ferroptosis, inflammatory response (NF- $\kappa$ B signaling), apoptosis, and fibrosis induced by doxorubicin through the involvement of NLRP3 and MyD88-related pathway (257, 258). A recent pre-clinical study reported that empagliflozin can also improve the cardiac dysfunction

induced by anti-VEGFR/PDGFR multi-TKI sunitinib, *via* regulation of cardiomyocyte autophagy, in turn mediated by the AMPK-mTOR signaling pathway (260).

## Late Inward Sodium Current Inhibitors

Selective inhibitors of late inward sodium current (INaL), such as ranolazine, have proven effective in treating experimental HF in several experimental models of cardiac dysfunction given its antiarrhythmic, anti-ischemic, and ATP-sparing features. Experimental evidence suggests that anthracyclines indirectly induce INaL hyperactivation, resulting in cytosolic calcium overload (261–263). INaL hyperactivation contributes to mitochondrial calcium depletion and dysregulation that, in turn, triggers mitochondrial ROS generation (oxidative stress), as well as NAD(P)H and ATP depletion (energetic stress); as a result, these events lead to cardiomyocyte impairment, diastolic dysfunction, and HF progression (261, 262, 264). Importantly, in animal models of doxorubicin-induced cardiotoxicity, ranolazine administration attenuated diastolic cardiac dysfunction and prevented worsening of systolic function by reducing oxidative stress and cardiomyocyte functional derangements (261, 262, 264). Moreover, ranolazine limited trastuzumab-induced cardiac dysfunction in mice by acting as a regulator of cardiac redox balance (265). In a very small randomized clinical study on 24 low-risk patients with diastolic dysfunction induced by anthracycline-based or fluoropyrimidine/platinum-based therapies, patients were treated for 5 weeks with ranolazine or standard therapy, observing a complete recovery from diastolic dysfunction in all subjects in ranolazine group (12 patients) (266). Thus, the therapeutic use of this drug is promising, although needs validation in large clinical trials specific for each type of chemotherapy.

## Phosphodiesterase-5 Inhibitors

Phosphodiesterase-5 inhibitors, such as sildenafil and tadalafil, were demonstrated to induce cardioprotective effects in animal models affected by doxorubicin cardiac toxicity (267–269). **Sildenafil** demonstrated cardioprotective activity against anthracycline-induced cardiac dysfunction by inducing the opening of mitochondrial  $K_{ATP}$  channels, leading to preserving mitochondrial potential and functions, myofibrillar integrity, and preventing cardiomyocyte apoptosis (267). The cardiac effects of sildenafil were also suggested to be dependent on the NO-signaling pathway since its protective activity was abolished by both L-NAME (inhibitor of NOS) and 5-hydroxydecanoate (inhibitor of ATP-sensitive  $K^+$  channels) (270). **Tadalafil's** effects on cardiotoxicity reduction, instead, were suggested to be mainly due to NO-mediated increases of protein kinase G (PKG) activity and cGMP signaling, which is significantly reduced by doxorubicin administration (268, 269).

## Metabolic Agents

**Butyric acid**, a short-chain fatty acid produced daily by the gut microbiota, has proven beneficial in models of cardiovascular diseases (271) [reviewed in (272)]. A novel butyric acid derivative, phenylalanine-butyramide (FBA), has

been shown to protect animal models from doxorubicin-induced cardiotoxicity by decreasing oxidative stress and improving mitochondrial function (273). Of note, FBA prevented doxorubicin-induced cardiomyocyte apoptosis, left ventricular dilatation, and fibrosis (273).

Another metabolic agent,  **$\beta$ -hydroxybutyrate (BHB)**, produced by fatty-acid oxidation in the liver under the fasting state, was shown to play a cardioprotective role in diabetic and HF with preserved ejection fraction (HFpEF) mouse models, when administrated as a dietary supplement or directly injected (274, 275). Interestingly, BHB was also reported to induce protection against anthracycline-induced cardiac function decline and partially reverted the maladaptive remodeling, characterized by increased cardiomyocyte size and decreased fibrosis (276). *In vitro*, BHB administration reduces oxidative stress and ameliorates mitochondrial functions, decreasing cardiomyocyte cell injury and apoptosis (276).

## Statins

Statins reduce cholesterol synthesis by inhibiting the enzyme HMG CoA reductase. However, statins have emerged as pleiotropic factors playing a positive role on the cardiovascular system, including ROS production and oxidative stress, and the consequent cardiac mitochondrial dysfunction [reviewed in (277, 278)]. Importantly, the treatment of breast cancer patients undergoing anthracycline-based therapy with statins has been reported to be associated with a lower risk for HF and to prevent the decrease of the left ventricular ejection fraction (279–282). A similar cardioprotective activity of statins was reported for trastuzumab-based therapies (283).

## Growth Factors

Administration of the growth factor **Neuregulin-1 (NRG1 $\beta$ )** has been shown to improve cardiac function following injury in adult mice (127, 134) [reviewed in (110, 133)] and in HF patients (135, 136) [reviewed in (137)]. Importantly, administration of NRG1 $\beta$  has also been shown to protect cardiac myocytes from anthracycline-induced apoptosis (134, 167, 284, 285) [reviewed in (286)]. Further, NRG1 administration in the zebrafish model was reported to reduce cardiomyocyte apoptosis induced by the multi-TKI ponatinib (200) [reviewed in (197)]. However, NRG1 $\beta$  is not clinically relevant as a therapy for cardiomyopathy induced by anticancer drugs because of its well-established cancer-promoting role. To solve this issue, an engineered bivalent NRG1 (NN), which preferentially induces ERBB4 homodimer formation in cardiomyocytes, has been developed and shown to protect against doxorubicin-induced cardiotoxicity, maintaining the same cardioprotective properties of NRG1 but with reduced pro-neoplastic potential (287). Nevertheless, although up to now there is no evidence in the literature about detrimental side effects in response to bivalent NRG1, NN has not been recruited into a clinical trial yet. Further studies are therefore recommended to assess if this combinatorial treatment is sufficient to mitigate the cardiotoxic side effects of chemotherapeutic agents.

**Granulocyte colony-stimulating factor (G-CSF)** is a hematopoietic growth factor that affects proliferation and

differentiation, especially of progenitors of the neutrophil and granulocyte lineages, therefore it is currently used clinically in combination with doxorubicin to counteract doxorubicin-induced myelosuppression (288). Interestingly, a role for G-CSF has also been suggested in doxorubicin-induced cardiomyopathy. Indeed, an attenuation of cardiomyocyte atrophic degeneration and a decrease of myocardial fibrosis have been reported after G-CSF administration in doxorubicin-treated mice (289). Intriguingly, G-CSF was suggested to exert an anti-atrophic and anti-inflammatory activity directly on cardiomyocytes (289).

Among stromal cells, the beneficial role of endothelial progenitor cells (EPCs) has emerged to counteract the cardiotoxicity of cancer therapies. For example, **erythropoietin (EPO)** has been shown to promote angiogenesis by increasing the number of EPCs, thereby improving cardiac function after doxorubicin treatment (290).

## Other Strategies

A few other strategies were suggested to reduce the adverse cardiovascular side effects of common chemotherapies and targeted therapies. In this regard, the sulfur-containing amino acid **taurine** (2-aminoethanesulfonic acid) has been shown to exert beneficial effects in CHF, ischemic heart disease, hypertension, atherosclerosis, and diabetic cardiomyopathy (291). Intriguingly, taurine was also shown to reduce cisplatin-induced cardiotoxicity by suppressing the generation of ROS, ER stress, and inflammation (102). **Apocynin**, a specific NADPH oxidase inhibitor, has been shown to reduce cisplatin-induced oxidative stress, inflammation and apoptosis (101).

Preclinical studies demonstrated that **fenofibrate**, a PPAR $\alpha$  activator, counteracted doxorubicin-induced cardiotoxicity in mice by increasing circulating EPCs, stimulating cardiac NO activation and inducing the production of pro-angiogenic factors such as SDF-1 and VEGF (292).

Besides molecular strategies, **remote ischemic preconditioning (RIPC)**, which consists of reversible repetitive interruptions in blood flow, ischemia, and reperfusion, seems a good approach to reduce anthracycline-induced cardiotoxicity (293). Indeed, large animals, subjected to RIPC before each doxorubicin injection, have shown a preserved cardiac contractility and mitochondrial integrity, concomitantly with a higher cardiac performance and reduced fibrosis (293).

## CONCLUSION AND FUTURE PERSPECTIVES

Although anticancer therapies greatly improve survival and quality of life of oncological patients, their negative impact on cardiac well-being is a very critical issue. In addition to common risk factors, such as age, hypertension, arrhythmias, and coronary disease, it has emerged the identification of genetic variants related to an increased predisposition to cardiotoxicity of chemotherapies and targeted therapies, in particular for anthracyclines and anti-HER2 therapies. Thus, the development of individualized treatments, based on the forecast of the cardiotoxic side effects, may acquire a considerable clinical

relevance for the future perspective. Importantly, the cellular and molecular mechanisms mediating the cardiotoxicity of common classes of chemotherapy and targeted therapy drugs are emerging, providing a rationale for the development of novel strategies for cardioprotection. Recent clinical trials have tested multiple cardioprotective drugs, highlighting the ability of some of them in counteracting or limiting the cardiotoxic effects of anticancer treatments. However, many of these therapeutic strategies still have certain limits and need some precautions. Among them, the lack of validation in large clinical trials, the underlying molecular mechanisms still not fully understood, as well as the risk-benefit controversies. In this regard, it is extremely important to take into account the tolerability of the adverse effects that these therapies may entail, including fatigue and dizziness, in patients already fatigued by antitumoral therapy.

Despite multiple cellular and molecular mechanisms being suggested to mediate the cardiotoxic effect of anti-cancer drugs, cardiomyocyte death has emerged as the major cause of long-term irreversible cardiac disfunction. These important side effects have been documented for anthracyclines, fluoropyrimidines, and alkylating drugs. This is because lost cardiomyocytes cannot be efficiently regenerated due to the very low ability of the adult mammalian heart to produce new cardiomyocytes (294, 295) [reviewed in (296)]. Although the cytotoxic effect of anticancer treatments resides on a wide range of biological mechanisms, the development of strategies aiming at increasing cardiomyocyte survival is thus encouraged to reduce anticancer drug-induced cardiomyocyte death and the consequent permanent damage. In the future, the administration of cardiomyocyte survival factors flanking chemotherapy and targeted therapies should be further explored. In this regard, a plethora of factors and signaling pathways has been shown to trigger endogenous cardiomyocyte proliferation for cardiac regenerative strategies [reviewed in

(296)], thus their modulation may be also explored for cancer patients with permanent damage by anticancer drugs. Some of these factors also regulate cardiomyocyte survival, thus their modulation may be tested as a preventive strategy to reduce permanent cardiotoxic effect of anticancer drugs. Obviously, the potential interfering with the action of the antineoplastic treatments should be carefully evaluated.

In conclusion, cardiovascular adverse effects resulting from antineoplastic therapies are important concerns for the health of cancer patients and could question the choice of undertaking or interrupting treatments. Nowadays, some drugs have been clinically tested to counteract the cardiotoxicity related to anticancer care, and we here propose a further evaluation of factors that up to now are mainly known for their role in cardiomyocyte proliferation and survival, as promising strategies for protection and/or regeneration of the cardiac tissue. Moreover, an increasing synergistic effort would be required for the oncologic and cardiologic research fields to assure cancer patients a long-term relapse-free survival and high-quality cardiovascular health.

Cardiovasc. Med.* 9:882167. doi: 10.3389/fcvm.2022.882167

**Background:** Immune checkpoint inhibitors (ICIs) have achieved acknowledged progress in cancer therapy. However, ICI-associated cardiotoxicity as one of the most severe adverse events is potentially life-threatening, with limited real-world studies reporting its predictive factors and prognosis. This study aimed to investigate the real-world incidence, risk factors, and prognosis of ICI-related cardiotoxicity in patients with advanced solid tumors.

**Methods:** Electronic medical records from patients with advanced solid tumors receiving ICIs in the First Affiliated Hospital of Xi'an Jiaotong University were retrospectively reviewed. All patients were divided into the cardiotoxicity group and control group, with logistic regression analysis being implemented to identify potential risk factors of ICI-related cardiotoxicity. Furthermore, survival analysis was also performed to investigate the prognosis of patients with ICI-related cardiotoxicity.

**Results:** A total of 1,047 participants were enrolled in this retrospective study. The incidence of ICI-related cardiotoxicity in our hospital is 7.0%, while grade 3 and above cardiotoxicity was 2.4%. The logistic regression analysis revealed that diabetes mellitus [odds ratio (OR):1.96, 95% confidence interval (CI): 1.05–3.65,  $p = 0.034$ ] was an independent risk factor, whereas baseline lymphocyte/monocyte ratio (LMR) (OR: 0.59, 95% CI: 0.36–0.97,  $p = 0.037$ ) was the protective factor of ICI-related cardiotoxicity. Survival analysis indicated that severe cardiotoxicity ( $\geq$  grade 3) was significantly correlated with bleak overall survival (OS) than mild cardiotoxicity ( $\leq$  grade 2) (8.3 months vs. not reached,  $p = 0.001$ ). Patients with ICI-related overlap syndrome had poorer overall survival than patients with mere cardiotoxicity (9.4 vs. 24.7 months,  $p = 0.033$ ). However, the occurrence of ICI-related cardiotoxicity was not significantly associated with the OS of overall population with solid tumors. Subgroup analysis showed that lung cancer and PD-L1 usage were significantly correlated with a higher incidence of severe cases.

**Conclusion:** Immune checkpoint inhibitor-related cardiotoxicity is more common in the real-world setting than the previously published studies. Diabetes mellitus and baseline

LMR are the potential predictive biomarkers of ICI-related cardiotoxicity. Although ICI-related cardiotoxicity is not correlated with the prognosis of these patients in our cohort, a systematic and comprehensive baseline examination and evaluation should be performed to avoid its occurrence.

**Keywords:** solid tumor, cardiotoxicity, rechallenge, risk factors, immune checkpoint inhibitor (ICI), prognosis

## INTRODUCTION

Immune checkpoint inhibitors (ICIs) mainly act on the activation of T cells to fight against tumor cells. There are currently FDA-approved drugs that target cytotoxic T-lymphocyte-associated antigen-4 (CTLA-4), programmed cell death protein 1 (PD-1), and programmed cell death ligand 1 (PD-L1). Although ICI-related adverse effects are overall less severe than chemotherapy, there are potentially lethal adverse effects, such as cardiotoxicity, neuromuscular toxicity, and pulmonary toxicity.

The first case of fatal ICI-related myocarditis was reported by Läubli et al. in 2015 (1), in a 73-year-old patient with metastatic melanoma who developed ICI-associated myocarditis after receiving pembrolizumab, leading to acute heart failure. Two cases of fulminant myocarditis were reported in 2016. Both patients became symptomatic within 2 weeks of administration and aggravated rapidly, leading to death within a short period despite the admission of high-dose glucocorticoid and supportive care. These two cases of severe cardiotoxicity warned clinicians of the security of ICIs (2).

Cardiotoxicity associated with ICIs is broadly classified into myocarditis, pericarditis, and arrhythmia. Other clinical manifestations, such as hypertension, Takotsubo-like syndrome, myocardial ischemia, and myocardial infarction, are less reported (3, 4). In addition, some studies have roughly divided them into inflammatory (including myocarditis, pericarditis, etc.) and non-inflammatory (arrhythmia, myocardial infarction, etc.).

Early studies showed that the incidence of ICI-related cardiotoxicity is less than 1% (5). However, as Ganatra et al. (6) stated, the increasing application of ICIs in real-world and the diverse presentation of cardiotoxicity suggest a higher incidence of cardiotoxicity than previously reported. In addition, subclinical cases and increased awareness of toxicity may also be the contributing factors. Among these classifications, myocarditis maintained the highest incidence and fatality rate, as well as the worst prognosis. However, the presentations of cardiotoxicity in real-world were not separated. It is not rare for myocarditis to occur simultaneously with arrhythmia or pericarditis. Studies have found that approximately 19% of patients with pathologically defined cardiotoxicity developed arrhythmias (7). Two patients with fulminant myocarditis reported in 2016 also developed complete atrioventricular conduction block (2). The pathophysiological manifestation suggested the infiltrated T cells and macrophages in the conduction system. As reported, atrial fibrillation, ventricular arrhythmias, and conduction disturbances were detected in 17–30% of patients with ICI-related cardiotoxicity, of whom 3–13% had mere arrhythmias without myocarditis (8). Although the mechanism is unclear, the investigators concluded

that there may be underlying undiagnosed myocarditis (8). There are limited studies on ICI-related pericardial disease. In addition, the incidence is unclear due to the lack of cardiovascular monitoring during ICI clinical trials but maybe more common than previously recognized. In an evaluation based on VigiBase, Salem et al. included 95 cases of pericardial disease associated with ICI, of which 60% were severe and 21% were associated with death (7). Unlike myocarditis, the incidence of pericarditis did not increase significantly with combination immunotherapy. In addition, the study found that more than half of the cases with pericardial diseases were reported in patients with lung cancer (7). Based on the preclinical and clinical studies, several possible influencing factors of ICI-related pericardial involvement were proposed. Given the disproportionately high incidence of pericardial disease in patients with lung cancer and synergy between radiotherapy and immunotherapy is considered a possible driver.

In the previous studies, autoimmune disease, prior heart disease, and combined ICI therapy can be the probable risk factors. Results are mostly derived from databases based on overall irAEs with few real-world studies based on cardiotoxicity. Therefore, we conducted a real-world retrospective study based on the whole immunotherapy population to explore the risk factors for ICI-related cardiotoxicity.

## MATERIALS AND METHODS

### Patients

Patients diagnosed with advanced solid tumors who were hospitalized from January 2020 to June 2021 at the departments of the medical oncology, surgical oncology, and radiation oncology at the First Affiliated Hospital of Xi'an Jiaotong University were included. We retrospectively screened patients into two groups according to whether cardiotoxicity happened during the administration of ICIs. Suspected cases were assessed mainly according to Bonaca diagnostic criteria (9). There were also cases that does not meet the criterion. In addition to that, we also consider ICI-related myocarditis according to the following two points:

1. Concurrent multi-organ damage with abnormal cardiac biomarkers responding to corticosteroids. Infection and autoimmune diseases were excluded.
2. Dynamical change in cardiac biomarker with ICI medication responding to corticosteroids. Infection and autoimmune diseases were excluded.

Immune checkpoint inhibitor-related pericarditis and arrhythmia were diagnosed according to Naranjo score: Suspected patients who suffered from cardiac damage during ICI therapy with a Naranjo scores  $\geq 5$  were included in the cardiotoxicity group.

Patients were categorized as “severe” cardiotoxicity if they displayed a grade 3–5 toxicity according to criteria adapted from the Common Terminology Criteria for Adverse Events V.5.0 (Table 1). Patients were categorized as “mild” cardiotoxicity if they displayed a grade 1–2 toxicity.

## Statistical Analysis

Continuous variables are statistically described by means  $\pm$  standard deviation (subject to normal distribution) or interquartile spacing (not subject to normal distribution); categorical variables are expressed in terms of number and percentage of cases. The SW test was used for the normality test, and one-way ANOVA was used for the variance homogeneity test. If the continuous variable obeys the normal distribution and the variance is homogeneous, the independent sample *t*-test is used, otherwise, the non-parametric rank sum test is used for statistical analysis. Categorical variables were statistically analyzed by the chi-square test or Fisher’s exact probability. All patients were divided into occurrence group and non-occurrence group based on whether cardiotoxicity occurred during ICI treatment, with the univariate logistic regression analysis being exploited to investigate the possible risk factors of cardiotoxicity. Ultimately, the variables with  $p < 0.05$  in univariate analysis were included in multivariate logistic regression analysis. All statistical analyses were performed in SPSS 23.0 and R 4.1.1 for Windows 64.0. Multiple imputations were used to supplement missing data.

## Ethical Approval and Informed Consent

This study was conducted in strict accordance with the requirements of the Declaration of Helsinki. Our research also passed the ethics review of the First Affiliated Hospital of Xi’an Jiaotong University (no: XJTU1AF2020LSK-262).

## RESULTS

### Characteristics of the Whole Population

From January 2020 to July 2021, a total of 1,492 patients with advanced solid tumors were hospitalized and treated with ICIs in the departments of medical oncology, surgical oncology, and radiation oncology. A total of 391 patients who did not meet the requirements were excluded, and a total of 1,101 patients who met the research criteria were screened. There were 127 patients with cardiac damage, of which 54 patients did not meet the diagnostic criteria. In the end, 974 patients did not develop cardiotoxicity, and 73 patients developed ICI-related cardiotoxicity, including 25 patients with severe cardiotoxicity and 48 patients with mild cardiotoxicity (Table 2).

Among the 1,047 patients treated with ICI, there were 713 male patients (68.1%) and 334 female patients (31.9%). Most of the patients were younger than 65 years (673 cases, 64.3%), and the physical performance score was mostly 0–1

(866 cases, 82.7%). In terms of cancer types, respiratory tumors (360 cases, 34.4%) and digestive tumors (496 cases, 47.4%) accounted for the majority, followed by urethral tumors (83 cases, 7.9%) and malignant melanoma (43 cases, 3.9%). Other tumor types included skin tumors, mediastinal tumors, head and neck tumors, genital neoplasm, sarcomas, and other tumor types. There were 220 (44.4%) gastrointestinal patients involved in the digestive tumor group, whereas 78 patients (21.7%) with small-cell lung cancer were involved in the respiratory tumor groups. Heart disease (74 cases, 7.1%), diabetes (115 cases, 10.9%), and hypertension (241 cases, 23.0%) were the common comorbidities. There were 379 patients (36.2%) with a history of smoking and 89 patients (8.5%) with a family history of tumors. Most patients received ICI combined chemotherapy (975 cases, 93.1%). PD-1 was the most predominantly used ICIs in our cohort, accounting for 92.0% of cases. In the case of later-line immunotherapy, prior treatment included chemotherapy, radiotherapy, targeted therapy, and antiangiogenic therapy. During the course of immunotherapy, 128 patients developed ICI-associated pneumonia (12.2%), and 380 patients developed ICI-associated thyroid dysfunction (36.3%).

### Risk Factors of Immune Checkpoint Inhibitor-Related Cardiotoxicity

Among the enrolled patients, 73 (7.0%) developed cardiotoxicity, including 48 mild cases (4.6%) and 25 severe cases (2.4%). Among the 115 patients with combined diabetes, 14 developed cardiotoxicity (12.2%). Whereas the occurrence rate of ICI-related cardiotoxicity among patients without diabetes was 6.3%, difference between these two groups was statistically significant ( $p = 0.033$ ). Besides, patients who developed cardiotoxicity have lower LMR ( $p = 0.01$ ). Respiratory tumors maintained the highest incidence of cardiotoxicity among all cancer types (8.6%), but there was no significant difference in the incidence of cardiotoxicity among tumor types. Combined cardiac diseases, ICI agents, history of previous antitumor therapy, and treatment modes have no correlation with the occurrence of cardiotoxicity. In terms of baseline laboratory levels, patients who suffered from cardiotoxicity have a lower lymphocyte ratio than patients without cardiotoxicity. But the difference was not statistically significant ( $p = 0.066$ ). In addition, our research showed that the occurrence of ICI-related pneumonia ( $p = 0.005$ ) and thyroid dysfunction ( $p < 0.005$ ) during the course of ICI treatment were significantly associated with the occurrence of cardiotoxicity. Although most of the other two toxicities appear before cardiotoxicity, we cannot yet explain the relationship between ICI-related cardiotoxicity and ICI-related pneumonia or thyroid dysfunction. But this correlation suggests a link between adverse effects of different systems, and the presence of one toxicity may warn of another that may be more serious.

The univariate logistic regression analysis found that combined diabetes (OR = 2.05, 95% CI: 1.07–3.71,  $p = 0.023$ ) may be a risk factor for cardiotoxicity, whereas lower baseline LMR (OR = 0.58, 95% CI: 0.35–0.93,  $p = 0.027$ ) may be a protective factor (Figure 1). Ultimately, the multivariate regression analysis suggested that diabetes (OR = 1.96, 95% CI: 1.05–3.65,  $p = 0.034$ ) was an independent risk factor for

**TABLE 1** | Criteria for myocarditis severity scoring.

Grade	Criteria
1 <sup>a</sup>	Elevated biomarkers without symptoms <sup>b</sup> (e.g., dyspnea, chest pain, etc.)
2	Elevated biomarkers without symptoms but not requiring patient hospitalization
3	Elevated biomarkers without symptoms requiring patient hospitalization (not requiring intensive care unit level of care); abnormal cardiovascular diagnostic studies (echocardiography showing reduction in LV function or wall motion abnormalities; abnormal cardiac MRI)
4	Deterioration of grade 3 clinical status or requirement for ICU level of care for cardiac symptoms with evidence of decreased cardiac output (cardiogenic shock) or arrhythmia
5	Death of the patient refractory to medical therapy

LV, left ventricular; MRI, magnetic resonance imaging; ICU, intensive care unit.

<sup>a</sup>CTCAE5.0 released in 2017 does not include grade 1 myocarditis. But this criterion cannot reflect the whole situation of the occurrence of myocarditis. This table is based on Bonaca and CTCAE4.0.

<sup>b</sup>Biomarkers for myocarditis are markers of myonecrosis, including cardiac troponin, CK-MB, or total CK.

the occurrence of ICI-related cardiotoxicity. In addition, lower baseline LMR (OR = 0.59, 95% CI: 0.36–0.97,  $p = 0.037$ ) was a protective factor (**Figure 1**).

## Severity of Myocarditis

The population with ICI-related cardiotoxicity included 48 mild cases and 25 severe cases (**Table 3**). Among them, 4 patients (5%) died in hospital. All in-hospital died patients were severe cardiotoxicity. When cardiotoxicity occurs, echocardiography was abnormal in 20 cases (26.3%), mainly with abnormal wall motion. A total of 24 patients (31.6%) had an abnormal electrocardiogram, including ST-T abnormality, conduction block, and other changes. In addition, 30 patients (41.1%) in the subgroup suffered from cardiotoxicity and concurrent ICI damage of other systems, among which abnormal liver function, myositis, skin rash, and abnormal thyroid function were more common.

Cardiotoxicity happened mainly in men (56, 76.7%). In terms of cancer types, the proportion of severe cases in respiratory tumors was significantly higher than in other tumors ( $p = 0.045$ ), whereas the proportion in digestive tumors was significantly lower than other tumors ( $p = 0.014$ ). The ICI agents were mainly PD-1 (65, 89.0%), of which 19 cases (29.2%) were severe, whereas 8 cases received PD-L1, and 6 cases (75.0%) were severe. The difference between the two groups was statistically significant ( $p = 0.008$ ). We did not find that inflammatory parameters, such as NLR, PLR, and LMR, were associated with the severity of cardiotoxicity. Other indicators, including ECOG score, comorbidities, smoking history, family history, prior antitumor therapy, and treatment mode, were not significantly associated with the severity of cardiotoxicity. In addition, unlike the general population, the occurrence of ICI-related thyroid dysfunction ( $p = 0.120$ ) and ICI-related pneumonia ( $p = 0.327$ ) was not significantly associated with the severity of cardiotoxicity. There was no statistically significant difference in the occurrence time of mild and severe cardiotoxicities (median occurrence time: 105 vs. 134 days,  $p = 0.345$ ) (**Figure 2**).

## Survival Analysis

Survival analysis was performed in patients with or without cardiotoxicity. We investigated the difference with overall survival in these patients. The median follow-up time

was 19.0 months. There was no significant difference with median overall survival time (mOS) between the two groups without cardiotoxicity and those with cardiotoxicity (29.1 vs. 24.7 months,  $p = 0.184$ ) (**Figure 3A**). The mOS of severe cardiotoxicity was 8.3 months, while the mOS of mild cardiotoxicity was not reached ( $p = 0.001$ ) (**Figure 3B**).

Survival analysis was performed on the subgroups of patients with respiratory tumors and digestive tumors due to different prognoses of different tumor types. There was no statistically significant difference between the two groups with or without cardiotoxicity in the respiratory tumors ( $p = 0.360$ ) (**Figure 4A**). The mOS between the two groups without cardiotoxicity in the digestive system and those with cardiotoxicity was 21.6 and 15.3 months, respectively (**Figure 4B**). But the difference was also not statistically significant ( $p = 0.509$ ). For all patients with cardiotoxicity, mOS was 17.0 months.

In addition, we also compared the survival difference between the groups with mere cardiotoxicity and those with concurrent cardiotoxicity and other toxicities. The mOS with mere cardiotoxicity was 24.7 months, and the mOS in the group with overlap syndrome was 9.4 months (**Figure 5A**). The difference was statistically significant ( $p = 0.033$ ). In 2020, Dolladille et al. (10) analyzed the clinical characteristics of early and late cardiac adverse reactions through retrospective analysis of multicenter cases and data from the VigiBase using 90 days as a cutoff. They found differences in the characteristics of early and late cardiac cardiotoxicities. We furtherly plotted the survival curves of the two groups of patients with the occurrence time before 90 days and after 90 days. However, there was no significant difference between the two groups (**Figure 5B**).

## Immune Checkpoint Inhibitor Rechallenge

Current guidelines suggest that restarting ICI is not recommended for grade 2 and above cardiotoxicity. We also strictly follow the recommendations in our clinical work. However, the complexity of real-world research results in patient diversity. In our study, some patients persisted in restarting ICI despite being fully informed of the risks. In the follow-up of patients who developed cardiotoxicity, there were 5 additional patients with grades 2 and 3 myocarditis who readmitted ICI after recovery (**Figure 6**). Only one of the five patients who

**TABLE 2 |** Characteristics of the whole population.

Characteristics	Groups	Number of patients (ratio) <sup>a</sup>

had grade 3 myocarditis suffered grade 2 myocarditis after the rechallenge of ICI. No other grade 3 and above ICI toxicity were found in all patients. Following up for more than 1 year, only one case died of disease progression. The remaining patients were all

alive. According to our investigation, the ICI rechallenge seems relatively secure. However, considering the small sample size in our cohort, more relevant studies are needed in the future to identify the safety of ICI rechallenge.

## DISCUSSION

We found that the incidence of cardiotoxicity was 7.0%, which was higher than the previously reported. By collecting the cardiovascular risk factors of the enrolled patients, we found that diabetes was an independent risk factor for the occurrence of cardiotoxicity. This conclusion can be seen in the retrospective study of Mahmood et al. (11). Through a multicenter retrospective study of 35 patients, they found that myocarditis was more common in patients with diabetes mellitus, especially in patients receiving a combination of ICI therapy. Although they ultimately failed to prove it an independent risk factor, their research suggested a certain direction. In our analysis, an exact association of diabetes with the development of cardiotoxicity was found. However, we did not find an association

between other cardiovascular risk factors, such as hypertension and the occurrence of cardiotoxicity.

The effect of diabetes on the development of ICI-related cardiotoxicity may be related to the long-term chronic inflammation in patients with diabetes. Till now, diabetes has been regarded as a chronic inflammatory disease. The high-glucose environment of diabetes significantly increases the cytokines, such as interleukin 4(IL-4), interleukin 5(IL-5), interleukin 6(IL-6), interleukin 13(IL-13), and tumor necrosis factor $\alpha$  (TNF- $\alpha$ ). These cytokines maintained the balance of the autoimmune microenvironment. The chronic pathological state of immune imbalance caused by diabetes can promote many diseases (12–14). In addition, the oxidative stress produced by diabetes can also produce many inflammatory cytokines, such as TNF- $\alpha$ , IL-6, and transforming growth factor  $\beta$  (14).

The cytokine pathway has been confirmed to be closely related to irAEs in many studies (15). In addition, diabetes affects the number and activity of T cells, B cells, and NK cells in peripheral blood, and the result of immune imbalance may also play an important role (14). Moreover, whether diabetes, as an autoimmune disease, also plays an important role in irAEs like other types of autoimmune diseases remains to be further studied.

We also collected baseline inflammatory indicators, such as IL-6, C-reactive protein (CRP), and lactic dehydrogenase (LDH), of all patients and calculated NLR, PLR, and LMR. We found that lower baseline LMR was an independent risk factor for the development of cardiotoxicity. In previous studies, the correlation between peripheral lymphocyte levels and adverse reactions has already been investigated. In a study of risk factors

for cardiotoxicity based on more than 4,000 immunotherapy patients (16), the authors identified the association between low baseline peripheral lymphocyte levels and cardiotoxicity through a machine learning method. In a retrospective study of NSCLC, an association of LMR with irAEs was also found (17). Activated T lymphocytes in patients with tumors after using PD-1/PD-L1 antibodies can not only attack tumor cells, but also cause irAEs. According to the autopsy result of patients with cardiotoxicity as previously reported, lymphocytic infiltration was widely seen in the diseased tissue (2). Therefore, lymphocytes may play a key role in the response of irAEs. However, no direct correlation between peripheral lymphocyte count (or percentage) and the occurrence of cardiotoxicity was found in our cohort. Moreover, these indicators are often dynamic during tumor treatment. Therefore, how does their changing act on adverse reactions? What role do lymphocytes play in it? They deserve further discussion.

In terms of gender, ICI was used in more men than women in our study, possibly due to the higher tumor prevalence in male patients. In this study, male patients received ICI proportionally more often than female patients, but no significant association between gender and the development of myocarditis was found. One study found higher occurrence rate of ICI associated cardiovascular with men (18). Several additional studies had the same finding (7, 11, 19). However, another research found a different result that women were at higher risk of ICI-related myocarditis. These studies suggested the relationship of gender and the occurrence of ICI-related myocarditis. In addition, we found a higher incidence of ICI-related cardiotoxicity in patients with respiratory neoplasms than in other types of neoplasms. Salem et al. (7) also found a higher rate of ICI-related pericardial disease among patients with lung cancer. Basic research has found upregulation of PD-L1 in models of myocardial injury induced by ischemiareperfusion and hypothermia, which may be a cytokine-mediated mechanism of cardiac protection. Besides, radiation therapy in patients with lung cancer may present with potential exposure to cardiac antigens. Immune activation thereby conferring them a higher incidence of cardiotoxicity. As for the correlation between comorbid autoimmune diseases and cardiotoxicity, there were numerous

**FIGURE 4 |** Survival curve of the patients suffered respiratory tumor with or without cardiotoxicity (A); patients suffered digestive tumor with or without cardiotoxicity (B).

**FIGURE 5 |** Survival curve of the patients with mere cardiotoxicity and patients with concurrent cardiotoxicity and ICI targeted other functional disorder (A); occurrence time (time since ICI initiation to the occurrence of ICI-related cardiotoxicity) of 90 days before and after 90 days (B).

**FIGURE 6 |** Follow-up of patients who restart ICI therapy after suffering ICI-related cardiotoxicity.

reports of thymoma patients with ICI-related cardiotoxicity. Toi et al. (20) retrospectively recruited 137 patients with positive autoimmune antibody receiving ICI therapy. They

found that positive autoimmune antibody was significantly associated with a higher occurrence of irAEs and better clinical benefit in NSCLC. In addition, another study also suggested

a relationship between autoimmune antibodies and irAEs (20). Therefore, we are more cautious about ICI initiation in patients with autoimmune diseases in real-world. Therefore, patients with active autoimmune disease were excluded from our study. Because the treatment of active autoimmune diseases is contrary to tumor treatment, they can affect the judgment to response of tumor treatment and drug-related adverse reactions.

In addition to ICI-related cardiotoxicity, we also collected ICI-related thyroid dysfunction and pneumonia. We found that both of them have a certain correlation with the occurrence of cardiotoxicity. Although the onset of ICI-related pneumonitis or abnormal thyroid function does not completely precede the onset of cardiotoxicity, we cannot establish a causal relationship between them. However, this finding suggests that there may be a link between the toxicities occurring at different times targeting different organs. The occurrence of toxicities targeting the lung or thyroid may then alert clinicians the occurrence of cardiotoxicity. Besides, myositis, hepatitis, and pneumonia may be complicated by the occurrence of cardiotoxicity. In the cardiotoxicity population, a total of 30 (41.1%) patients had concurrent toxicities targeting other organs. In a study based on the Vigibase database, serious combined ICI-related adverse reactions accounted for 42% of adverse reactions, most of which were ICI-related myocarditis and myositis (21). In a multicenter study, 32% of myositis was associated with concurrent myocarditis (22). In addition, the mortality rate is the highest in patients with combined myocarditis and myasthenia gravis. Therefore, in patients with symptoms of ICI-related myositis, they should be alert to the occurrence of myocarditis.

Previous studies have demonstrated a possible correlation between irAEs and tumor prognosis. A meta-analysis (23) explored the relationship between ICI-related adverse drug reactions and clinical benefits. It was suggested that in patients receiving ICIs, the development of irAEs was positively correlated with objective remission rate (ORR), progression-free survival (PFS), and OS, irrespective of disease site, type of ICI, and irAE. ORR was better in patients with grade 3 or higher toxicity, but OS was worse. However, in this study, we only did the analysis in overall survival, and no significant difference was found between patients with or without cardiotoxicity.

Till now, the National Comprehensive Cancer Network (NCCN) guidelines do not recommend rechallenge of ICI after grade 2 and above myocarditis. Subclinical myocarditis was recommended continue the use of ICI with close detection. In a single-center retrospective study in 2019 (24), the investigators included 93 patients with grade 2 or higher toxicity, including 43 grade 2 events, 36 grade 3 events, and 14 grade 4 events. Taking the occurrence of the second toxicity as the endpoint, the final results suggested that the time since ICI use to the occurrence of the initial irAE was related to the occurrence of the second irAE. Besides, the severity of the second irAE was not more severe than the first one. They concluded that the risk-reward ratio of anti-PD-1 or anti-PD-L1 rechallenge

appears to be acceptable. However, patients with first ICI-related toxicity involving the heart were not included in this study. Conversely, there were also some studies restarting ICI after the occurrence of irAEs, resulting in recurrence of grade 5 toxicity in patients. Therefore, ICI rechallenge after irAEs is still controversial. Due to the small number of cases in our study, we cannot currently explain the safety of cardiotoxicity after restarting, because once cardiotoxicity occurs, it may be fatal drug toxicity, which is unacceptable for clinicians and patients' families. Moreover, the timing of ICI restarting among these patients also varied, and some patients even resumed ICI 1 month after ICI withdrawal. If there are large clinical studies to confirm the feasibility of restarting immunotherapy for ICI-related cardiotoxicity, the timing of restarting ICI will also be a major focus. Furthermore, there were many patients with grade 1 cardiotoxicity who continue to use immunotherapy under strict monitoring, and a small number of patients who suffered mild cardiotoxicity for not one time, but it does not affect the progress of tumor treatment.

## CONCLUSION

We retrospectively analyzed the risk factors of ICI-related cardiotoxicity in the whole population receiving ICI therapy. We found a higher incidence of ICI-related cardiotoxicity, and a high proportion of severe cases than previous reported in real-world situation. Patients with diabetes mellitus and low baseline levels of LMR have an increased incidence of cardiotoxicity, which should be closely monitored during the use of ICIs. Besides, the incidence of severe cardiotoxicity was correlated with shorter overall survival.

## SHORTAGE

Despite the advantages and potential insights on this study, there are some inevitable shortcomings in our study. First of all, some potential biases are still unavoidable due to the retrospective design of this study, such as investigator bias. Second, although the overall immunotherapy sample size we included is relatively large, the number of cardiotoxicity cases is relatively small, as well as the number of patients who rechallenge ICI. Finally, due to the serious lack of some data during the study period, we could not analyze the relationship between the baseline levels of some inflammatory markers (such as LDH, CRP, and cytokines) and the occurrence of cardiotoxicity. Hence, well-designed large-scale prospective studies are urgently needed in the future.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## ETHICS STATEMENT

This study involving human participants was reviewed and approved by the Ethics Review of the First Affiliated Hospital of Xi'an Jiaotong University (no. XJTU1AF2020LSK-262) and was conducted in strict accordance with the requirements of the Declaration of Helsinki. Written informed consent was not required due to the retrospective nature of the study.

Clinical Characteristics and  
Long-Term Outcomes of MINOCA  
Accompanied by Active Cancer: A  
Retrospective Insight Into a  
Cardio-Oncology Center Registry.  
Front. Cardiovasc. Med. 9:785246.  
doi: 10.3389/fcvm.2022.785246

**Background:** Clinical characteristics and long-term outcomes of patients with myocardial infarction with non-obstructive coronary arteries (MINOCA) and cancer are insufficiently elucidated.

**Objectives:** We sought to characterize these patients hospitalized in a tertiary cardio-oncology center and to find the potential determinants affecting their long-term mortality.

**Methods:** MINOCA was diagnosed in 72 of the 1,011 patients with consecutive myocardial infarction who underwent coronary angiography. Mortality rates and their determinants were analyzed within a median follow-up of 69.2 (37.8–79.9) months.

**Results:** Active cancer was identified in 21 (29.2%) of patients with MINOCA and in 113 (12.0%) patients with myocardial infarction and obstructive coronary artery disease (MI-CAD) ( $p < 0.001$ ). MINOCA patients with cancer were characterized by a higher incidence of anemia (47.6 vs. 21.6%,  $p = 0.03$ ) and more frequently Takotsubo syndrome (19.1 vs. 2.0%,  $p = 0.01$ ) than in non-cancer MINOCA. The troponin T/hemoglobin ratio was higher in both cancer MINOCA and MI-CAD groups when compared with their respective non-cancer patients (both  $p < 0.05$ ). The age and sex-standardized mortality rates were significantly higher in cancer MINOCA (26.7%/year) when compared with non-cancer MINOCA (2.3%/year,  $p = 0.002$ ) and in cancer MI-CAD (25.0%/year) vs. non-cancer MI-CAD (3.7%/year,  $p < 0.001$ ). Active cancer (HR 3.12, 95% CI 2.41–4.04) was independently associated with higher long-term mortality, while higher hemoglobin levels (HR 0.93, 95% CI 0.88–0.99, per g/dl) and a MINOCA diagnosis (HR 0.69, 95% CI 0.47–0.97) improved long-term survival.

**Conclusion:** Patients with MINOCA were comorbid with cancer more frequently than MI-CAD. In turn, an active malignancy was associated with an unfavorable long-term survival both in MI-CAD population and in patients with MINOCA.

**Keywords:** MINOCA, MI-CAD, cancer, anemia, cardio-oncology

## INTRODUCTION

Myocardial infarction with non-obstructive coronary arteries (MINOCA) is recognized if it meets the general criteria of myocardial infarction (MI) together with the absence of significant lesions in epicardial arteries in angiography (1). As shown in large MI registries, MINOCA concerns 1–13% of all patients with MI (2, 3). Recent reports indicate an unexpectedly unfavorable long-term prognosis in this group of patients. The SWEDEHEART registry included 9,092 patients with MINOCA, of whom 24% experienced a major cardiovascular event, and where 14% died within a mean follow-up period of 4.5 years (4).

The potential mechanisms responsible for MINOCA are heterogeneous (1, 5). According to the current knowledge, the underlying pathophysiological causes of MINOCA are grouped as coronary or non-coronary. Moreover, the latter are classified as myocardial disorders or as those that are typically extra-cardiac (6). Both historical (7) as well as current findings (8) indicate that hypercoagulable states, including the inherited thrombophilia, occurred in 15–25% of patients with MINOCA. This includes deficiency of protein C, protein S, or antithrombin. Additionally, the antiphospholipid syndrome was detected in 15.5% of patients. Concurrently, patients with cancer are a group that is at a particularly high prothrombotic risk, traditionally in the venous system (9). An analysis of the Surveillance, Epidemiology, and End Results involving nearly 280,000 patient pairs showed that the rate of arterial thromboembolic events was 4.7% in cancer patients compared with the 2.2% in controls (10). That predisposition for arterial thromboembolism, defined as MI, ischemic stroke, or peripheral arterial occlusion, has been confirmed recently in a large Danish population-based cohort study (1.5 vs. 0.8% in the 6-month observation, hazard ratio [HR]: 2.36, 95% confidence interval [CI]: 2.28–2.44) (11). Moreover, its occurrence among patients with cancer was associated with an increased risk of mortality (HR 3.28, 95% CI: 3.18–3.38) (11). As the arterial thromboembolic events immediately preceded cancer diagnosis and were correlated with the stage of cancer (10, 11), they can be considered paraneoplastic symptoms, which always require subsequent meticulous diagnostics toward a subclinical neoplastic process (12).

Recently, a review of the meta-regression analysis of nine studies including 26,636 patients with MINOCA has shown that 2.5% of them had a diagnosis of malignancy at presentation (13). Similar findings have been reported in the SWEDEHEART registry (14). Despite relatively low prevalence, both Nordenskjöld et al. (4) (HR: 2.40, 95% CI: 1.58–3.61,  $p < 0.001$ ) and Pelliccia et al. (13) (coefficient: 0.001, 95% CI:  $-0.001$  to  $0.001$ ,  $p = 0.01$ ) have found cancer as an independent predictor of death in patients with MINOCA. Another meta-analysis including a higher number of patients with MINOCA, i.e., 36,932, did not confirm a similar relationship (15). Therefore, we sought to characterize subjects with MINOCA and cancer hospitalized in a tertiary cardio-oncology center in order to investigate the potential mechanisms affecting their long-term outcomes.

## MATERIALS AND METHODS

As has been stated retrospectively, in a tertiary cardio-oncology center including closely cooperating departments of cardiology (168 hospital beds), cardiac surgery (80 beds), pulmonology and oncology (74 beds), and thoracic surgery (48 beds), 1,011 consecutive patients underwent coronary angiography between 2012 and 2017 due to the diagnosis of MI based on clinical symptoms, electrocardiographic findings, and the evolution of myocardial necrotic biomarkers (16). MINOCA was recognized in 72 (7.1%) subjects (**Figure 1**) based on the universal criteria of MI (positive cardiac biomarkers rising and/or falling in serial measurements, with at least one value above the 99th percentile as the upper reference limit and at least one clinical sign of infarction). An additional inclusion criterion was a lack of obstructive lesions narrowing epicardial coronary segments by more than 50% in angiography (1, 17). Patients with ST-segment elevation of at least 1 mm in at least two contiguous leads were classified as ST-segment elevation MI (STEMI), whereas patients without ST-segment elevation on admission were diagnosed as non-ST-segment elevation MI (NSTEMI) (18). In addition, 134 (13.3%) patients were identified with active cancer, defined as cancer diagnosed within the past 6 months, receiving antimitotic treatment during the last 6 months, recurrent, metastatic, regionally advanced, or inoperable (19) (**Figure 1**). In the analyzed period of time, five MI patients with advanced cancer did not undergo coronary angiography and

were therefore excluded from further analysis. The study protocol complied with the Declaration of Helsinki and was approved by the Jagiellonian University Medical College Ethics Committee (Consent No. 1072.6120.59.2018). All included patients gave informed consent.

## Patients Clinical and Laboratory Characteristics

Information on demographics, anthropometric parameters, cardiovascular risk factors, cardiovascular disease history, and comorbidities of all the study patients was gathered. Anemia was recognized if the hemoglobin level was <13 g/dl for men and <12 g/dl for women. The cut-off value for the thrombocytopenia was  $100 \times 10^3/\mu\text{l}$  (20). Pre-end-stage renal disease and end-stage renal disease was diagnosed when creatinine clearance calculated using the Cockcroft-Gault formula was lower than 30 ml/min. Finally, creatine kinase serum activity (IU/L, upper limit of normal: 170 IU/L), isoenzyme MB of creatine kinase (IU/L, upper limit of normal: 24 IU/L), and concentration of high-sensitive cardiac troponin T (ng/ml, upper limit of normal: 0.014 ng/ml) were measured on admission and at least one time within the first 24 h.

## Angiography

All coronary angiograms were analyzed off-line, using two contralateral projections for each artery at baseline and after angioplasty if applicable, by a cardiologist unaware of the clinical data. All coronary segments were carefully evaluated for the presence of visible thrombus, distal embolization, and degree of stenosis based on visual inspection (21, 22). In cases of borderline lesions between 40 and 70%, quantitative coronary angiography (QCA Quantcor, Siemens, Germany) was applied for precise assessment. According to the guidelines (1, 5), lesions narrowing the coronary artery by <50% were defined as insignificant. All patients with insignificant stenosis were divided into two groups with either i) normal coronary arteries or minimal intracoronary

irregularities with stenosis of <30% or with ii) mild to moderate lesions of at least 30 and <50%.

## Echocardiography

A two-dimensional transthoracic echocardiography was performed by a trained physician between the second and fourth day of hospitalization. It was performed at rest in a left decubitus position, using a Vivid S5 ultrasound (GE, Solingen, Germany) equipped with a multi-frequency harmonic transducer, 3Sc-RS (1.3–4 MHz). All measurements were carried out according to the recommendations of the American Society of Echocardiography and the European Association of Echocardiography (23). Standard parameters were collected to describe individual heart structures and enable their functional assessment. Screening for Takotsubo syndrome was also routinely conducted, the diagnosis of which was performed according to the InterTAK criteria (24), irrespective of the severity of coronary artery disease (25).

## Clinical Follow-Up

The length of hospitalization was collected from hospital records, whereas long-term all-cause mortality was obtained from the National Health Registry. The additional data regarding the cause of death were obtained from the Polish Office of Statistics. The causes of death were categorized as cancer, cardiovascular, other (the most common causes included respiratory system disease or accident/trauma), or unknown. Major cardiovascular causes of death included coronary artery disease, cerebrovascular disease, heart failure, or atherosclerosis.

## Statistical Analysis

Statistical analysis was performed with the SPSS Statistics software (Version 25.0.0.2, IBM, USA). Continuous variables were expressed as medians (interquartile range) and categorical variables as numbers (percentage). Continuous variables were

first checked for normal distribution using the Shapiro–Wilk test. Afterward, differences in the four groups were compared with an analysis of variance, followed by a *post-hoc* Bonferroni test if the data distribution was normal. Non-normally distributed data were analyzed *via* the Kruskal–Wallis test, and differences between the groups were identified using a test for multiple comparisons of mean ranks. Categorical variables were analyzed with the chi-square test or Fisher's exact test with a *post-hoc* z-test for comparison of column proportions with the Bonferroni method. The mortality rates were expressed as crude or age and sex-standardized for the European population based on Eurostat data available online (26). The Kaplan–Meier curves for overall mortality were constructed in order to estimate the survival rates, and a log-rank test with a Bonferroni-corrected threshold was performed to assess the differences in survival between the study groups. Finally, all independent variables with the potential to confound both the exposure and the outcome were included in the Cox proportional hazard regression model to determine independent predictors of long-term all-cause mortality. A two-tailed *p*-value of  $<0.05$  was considered statistically significant.

## RESULTS

Based on detailed angiographic and oncological characteristics, four groups of patients were created (**Figure 1**). Within 1,011 MI patients, active cancer and MINOCA were identified in 21 (2.1%) patients, whereas MINOCA without cancer was diagnosed in 51 (5.0%) subjects. Of the 939 remainders with type 1 MI with obstructive coronary artery disease (MI-CAD), 113 (11.2%) patients had active cancer and 826 (81.7%) had no evidence of active cancer. In 111 patients, the malignancy process was diagnosed before index MI, whereas new cancer was found during index hospitalization in two patients with MINOCA and in 21 with MI-CAD (**Table 1**).

Among the four groups, there were significant differences in the distribution of gender, anthropometric parameters, dyslipidemia, active smoking status, and initial clinical presentation ( $p < 0.01$  for each) (**Table 1**). The angiographic analysis also revealed a different proportion of epicardial thrombus in the compared groups ( $p = 0.02$ ). Hemoglobin levels were lower, whereas baseline high-sensitive troponin T was higher in both cancer groups compared with non-cancer

**FIGURE 2 |** The relationships between troponin T and hemoglobin level in the study groups. **(A)** Cancer MINOCA, **(B)** Non-cancer MINOCA, **(C)** Cancer MI-CAD, **(D)** Non-cancer MI-CAD, and **(E)** In both cancer groups, the ratio of troponin T to hemoglobin was higher than in the respective non-cancer groups. Data are shown as number (percentage) unless otherwise indicated, MINOCA, myocardial infarction with non-obstructive coronary artery; MI-CAD, myocardial infarction and obstructive coronary artery disease; NA, not applicable; p-value for differences in four groups based on a chi-square test with a post-hoc z-test for comparison of column proportions with the Bonferroni method (\*) or a log-rank test for multiple comparisons of survival curves with the Bonferroni-corrected threshold (\*\*), <sup>#</sup>p < 0.05 non-cancer MINOCA, <sup>^</sup>p < 0.05 non-cancer MI-CAD.

proposed ratio of troponin T to hemoglobin was higher in cancer patients with MINOCA and MI-CAD when compared with the respective non-cancer groups (Figure 2E). The time of hospitalization was insignificantly shorter in non-cancer MINOCA (4 (3–7) days) as compared with cancer MINOCA (6 (3–12) days), cancer MI-CAD (6 (3–9) days), and non-cancer MI-CAD (6 (4–8) days) and ( $p = 0.07$ ).

## Active Cancer Diagnosis Among MINOCA Patients

MINOCA was recognized significantly more often in cancer patients (21 of 134) compared with the non-cancer (51 of 877) cohort (15.7 vs. 5.8%,  $p < 0.001$ ). A higher percentage of women was found in both cancer and non-cancer MINOCA groups than in the respective MI-CAD populations ( $p < 0.05$  for both pairwise comparisons). A higher incidence of anemia was observed in cancer vs. non-cancer MINOCA group (47.6 vs. 21.6%,  $p < 0.05$ ), without a significant difference in thrombocytopenia (14.3 and 3.9%). In both groups, the vast majority of MIs were classified as NSTEMI (71.4 and 88.2%, respectively). Similar treatment regimens were found in both MINOCA subgroups (Table 1). Aspirin was used in 90.5 and 86.3% of patients, respectively, whereas P2Y12 inhibitor was used in approximately half of the patients in both groups. Only proton pump inhibitors were used less frequently in cancer than in non-cancer MINOCA patients (38.1 vs. 68.6%,  $p < 0.05$ ).

The echocardiographic screening showed more frequent Takotsubo syndrome in the oncological patients (19.1 vs. 2.0%,  $p = 0.010$ ), with almost the same distribution of

insignificant lesions in angiography in both groups (Table 1). Both epicardial thrombi and distal embolization were not found in cancer MINOCA and were reported only in the single non-cancer patients with MINOCA. Higher right ventricular systolic pressures ( $p = 0.03$ ) and lower left atrium diameters ( $p = 0.05$ ) (Table 2) were found in cancer vs. non-cancer patients with MINOCA with no differences in left ventricular ejection fraction (LVEF).

## Active Cancer in Patients With MI With vs. Without Obstructive Coronary Artery Disease

Active cancer was found more often in patients with MINOCA (21 of 72) compared to patients (29.2 vs. 12.0%,  $p < 0.001$ ) with MI-CAD (113 of 939) (Table 1). Men were almost two times as represented in the cancer MI-CAD group compared with the MINOCA subgroup (77.9 vs. 38.1%,  $p < 0.05$ ). Almost half of the patients had anemia in both groups, and both cancer groups presented with thrombocytopenia less frequently than anemia (Table 1) in a similar proportion when compared with respective non-cancer populations. In-hospital use of P2Y12 inhibitors (47.6 vs. 92.9%,  $p < 0.001$ ), proton pump inhibitors (38.1 vs. 74.3%,  $p = 0.001$ ), and statins (66.7 vs. 87.6%,  $p < 0.05$ ) was less frequent in cancer MINOCA than in cancer MI-CAD.

In half of the newly diagnosed neoplasms, the first symptom was bleeding associated with antiplatelet and/or antithrombotic treatment administered during index MI, including hematuria (26%), hemoptysis (13%), and bleeds from the gastrointestinal tract (13%). Genitourinary neoplasms were predominant in

**FIGURE 3 |** The effect of cancer and its type and MINOCA on long-term survival. **(A)** Diagnosis of cancer was associated with significantly reduced long-term survival ( $p < 0.001$ , gray, wide arrow), whereas MINOCA diagnosis improved ( $p = 0.048$ , black, narrow arrows) long-term survival. **(B)** Long-term survival in patients with lung cancer was lower than that in those with genitourinary cancer ( $p = 0.001$ ) or breast cancer ( $p = 0.018$ ). MINOCA, myocardial infarction with non-obstructive coronary artery; MI-CAD, myocardial infarction and obstructive coronary artery disease.

both patients with MINOCA and MI-CAD (38.1 and 31.9%, respectively), whereas breast cancer was more frequent in the MINOCA group (23.8 vs. 5.3%,  $p = 0.02$ ). There were significant differences neither in the locoregional and distant advancement of the neoplastic process nor in the anticancer treatment applied before the index MI (Table 1). The most commonly used chemotherapeutic agents in the MINOCA group were platinum compounds and taxanes. In turn, platinum compounds and fluoropyrimidines dominated in MI-CAD (Table 1).

Epicardial thrombus (12.4%) as well as distal embolization (8.0%) were observed numerically in a high percentage of cancer patients with MI-CAD but were not found in the cancer MINOCA group (Table 1). In the majority of cancer patients with MI-CAD, the significant atherosclerotic lesions were limited to one or two coronary arteries (77%). Most of these patients were treated with percutaneous coronary intervention (89.4%). In contrast, Takotsubo syndrome among patients with cancer was diagnosed only in the MINOCA group (19.1 vs. 0.0%,  $p < 0.05$ ) (Table 1). There were no significant differences in right ventricular systolic pressure ( $p = 0.18$ ) and LVEF ( $p = 0.28$ ), but significantly larger end-diastolic ( $p = 0.02$ ) and end-systolic ( $p = 0.03$ ) left ventricular (LV) diameters were identified in the cancer

MI-CAD group. Chemotherapy and radiotherapy administered before index MI did not affect LVEF ( $p = 0.59$ ), end-diastolic ( $p = 0.90$ ), or end-systolic ( $p = 0.86$ ) LV diameters (Table 2).

## Long-Term Mortality, Its Causes, and Predictors

The median follow-up time in patients with non-cancer MINOCA, non-cancer MI-CAD, cancer MINOCA, and cancer MI-CAD was 73.4 [33.7–81.7], 41.9 [28.1–73.5], 35.0 [6.2–77.2], and 17.3 [4.9–43.9] months, respectively ( $p < 0.001$ ). Both crude or age- and sex-standardized mortality rates as well as causes of death differed among the four groups (Table 3). As expected, the higher prevalence of cancer deaths was more pronounced in both oncological groups. In turn, cardiovascular causes of death were predominant in both non-cancer MINOCA and MI-CAD groups. Long-term survival was significantly higher in non-cancer MINOCA when compared with cancer MINOCA (HR 4.07, 95% CI 1.72–9.64,  $p = 0.002$ ) and in non-cancer MI-CAD when compared with cancer MI-CAD (HR 7.62, 95% CI 5.13–11.31,  $p < 0.001$ ). Concurrently, there were no significant differences in long-term survival between both cancer groups of MINOCA and MI-CAD (HR 0.76, 95% CI 0.45–1.28,  $p =$

**TABLE 4 |** The independent predictors of death in the whole group and in patients with MINOCA.

	Univariable model			Multivariable model

CI, confidence interval; HR, hazard ratio; LVEF, left ventricular ejection fraction; MINOCA, myocardial infarction with non-obstructive coronary artery.

0.31), as well as both non-cancer groups of MINOCA and MI-CAD (HR 0.80, 95% CI 0.50–1.28,  $p = 0.35$ ) (**Figure 3A**). The median survival time irrespective of the type of MI was 56, 39, 12, and 10 months for breast, genitourinary, gastrointestinal, and lung cancer, respectively (**Figure 3B**). A significantly better survival rate was found in patients with genitourinary cancer vs. lung cancer (HR 0.34, 95% CI 0.18–0.65,  $p = 0.001$ ) and in breast cancer vs. lung cancer (HR 0.39, 95% CI 0.18–0.85,  $p = 0.02$ ).

In the MINOCA group, there were no significant differences in the long-term survival between patients with vs. without Takotsubo syndrome (**Supplementary Figure 1**). There was also a significantly higher long-term mortality rate in cancer vs. non-cancer patients matched for age, gender, body mass index, diabetes, hypertension, and hyperlipidemia (**Supplementary Table 1** and **Figure 2**). A Cox proportional hazard regression limited to patients matched for demographic parameters and cardiovascular risk factors showed that unfavorable prognosis was associated with active cancer, a lower hemoglobin level, and age of older patients. Simultaneously, hypertension, hyperlipidemia, and better LVEF independently improved long-term survival (**Supplementary Table 2**).

In the whole group, age, female gender, cancer, anemia, and lower hemoglobin level were identified as associated with a higher mortality rate in a univariate model (**Table 4**). Using a Cox proportional hazard regression, an active cancer was independently associated with a higher long-term mortality rate, while higher hemoglobin levels and MINOCA diagnosis improved long-term survival (**Table 4**). A Cox proportional hazard regression limited to only patients with MINOCA showed that age, cancer, and LVEF were independently associated with a long-term mortality rate (**Table 4**).

## DISCUSSION

To our knowledge, this study is the first and most comprehensive analysis derived from a tertiary cardio-oncology center concerning the complex relationship between cancer and MINOCA, as well as its influence on long-term clinical outcomes. As shown, neoplasm has been identified more frequently in patients with MINOCA than in those with atherosclerosis and/or thrombus-based type 1 MI (defined as MI-CAD). However, a multivariable analysis showed that an active malignancy was associated with unfavorable long-term outcomes. We have also provided clinical features that characterized cancer patients with MINOCA, which might be useful in their differential diagnosis. It is important to note that the diagnosis of cancer in both MINOCA and MI-CAD groups was associated with an extremely high all-cause mortality in a 5-year observation. Moreover, a multivariable approach limited to only the MINOCA group showed that active cancer irrespective of age and lower left ventricular systolic function affected a higher mortality rate.

Patients with MI-CAD and cancer distinguished in our study were characterized by a highly unfavorable prognosis driven mostly by neoplastic disease. Although treatment of such patients should be strictly individualized, there are still limited data sufficiently addressing the optimal management of MI in patients with cancer (27). Further studies are warranted to establish an optimal antithrombotic regimen, especially in the acute phase, due to the proven high risk of stent thrombosis (9, 28). The results derived from the large Nationwide Inpatient Sample indicate that cancer in patients receiving percutaneous coronary intervention is common, but its prognostic impact depends on detailed oncological characteristics (29). Our results also indicate that, in both cancer and non-cancer MI-CAD patients, the rate of revascularization with the percutaneous coronary

intervention was almost 90% emphasizing current trends in interventional cardiology. While cancer patients with type 1 MI were historically less likely to receive primary percutaneous coronary intervention with first-generation drug-eluting stents mainly due to the need for a shorter course of dual antiplatelet therapy following bare-metal stents, the new drug-eluting stents requiring shorter antiplatelet therapy time have become more effective and as safe as bare-metal stents. According to the current registries, dual antiplatelet therapy was prescribed in only half of the patients with MINOCA, mainly in those with sinus rhythm, prior percutaneous coronary intervention, and active smokers (30).

In contrast, the prognosis in patients with MINOCA remains controversial, with the latest studies suggesting comparable (4, 31) or lower (15) long-term mortality rates in patients with MINOCA vs. MI-CAD. The abovementioned studies indicate that a history of cancer coexisting with 2–2.5% of patients with MINOCA (4, 13) is (13) or is not (15) an independent predictor of their long-term mortality. In our MINOCA and MI-CAD groups, a diagnosis of active cancer made before index MI was more common. This overrepresentation of neoplastic status was independently associated with unfavorable long-term survival. When compared with the available literature, such a high proportion of cancer patients is primarily a result of the structure of our center, as well as that of direct admissions from oncology and thoracic surgery departments to the cardiology ward. Interestingly, there is a visible trend toward more frequent admissions of cardio-oncology patients due to their prolonged survival time.

The etiology of MI in the oncological population is multifactorial. In previous studies, the role of cancer-induced immunological disorders, oxidative stress, prothrombotic state, and oncological treatment was underlined in MI development among cancer patients (32). Moreover, oncological patients are generally high-risk due to the significant prevalence of traditional cardiovascular risk factors, such as older age, hypertension, dyslipidemia, diabetes, obesity, or tobacco addiction (28). This was also corroborated in this current study. Most of the above-indicated factors contribute to the shifted oxidase-reductase balance and endothelial injury. This exacerbates coronary artery disease progression and promotes the rupture of atherosclerotic plaque associated with type I of MI, identified as MI-CAD (28, 32, 33) in our study. On the contrary, the influence of cancer and antitumor treatment is undeniable among MINOCA survivors. The rupture of non-obstructive plaque, distal embolization, hypercoagulable state with thrombus formation, transient artery spasm, microvascular dysfunction often caused by endothelial impairment, and supply-demand mismatch, among others, are all mechanisms responsible for MINOCA (5). It is worth noting that, each of these sequences of events might be triggered by both tumor and antineoplastic treatment (13). The classic chemotherapy drugs have been proven to damage the coronary arteries, mainly in their endothelium. Therefore, they can lead to acute thrombosis and coronary spasms (33). Drugs that particularly increase the risk of MI include fluoropyrimidines (5-fluorouracil, capecitabine, gemcitabine) and platinum compounds (33), which were also

often used among the analyzed patients. Moreover, combining chemotherapeutics from different groups, especially those mentioned above, significantly increases the risk of MI (33). However, there is a lack of original reports demonstrating the relationship between chemotherapy and MINOCA. Our study provides detailed angiographic and echocardiographic characteristics of cancer patients with MINOCA, shedding light on their potential relationships. These findings might be helpful in further research dedicated for personalized treatment in this demanding group of patients.

A long-term prognosis is associated with myocardial infarct size. As we have shown, both cancer and non-cancer patients with MINOCA were characterized by a better preserved global LV function and lower peak high-sensitive troponin levels compared with the corresponding MI-CAD groups. This indirectly indicates a lower myocardial injury rate and most likely a smaller infarct size in patients with MINOCA. These findings are in line with previous data showing that, among the MINOCA population, patients with heart failure with preserved LV ejection fraction (34, 35) predominated. Post-infarction myocardial remodeling is also less frequently observed in this group. There are at least a few potential explanations for this relationship. First, the smaller myocardial infarct size is a consequence of a higher prevalence of NSTEMI in MINOCA (8). Second, cardiac magnetic resonance imaging provides evidence that, in patients with MINOCA, only small foci of necrosis are often observed, while myocardial edema is the dominant abnormality (36).

In this study, hemoglobin levels were lower in both cancer groups, compared with respective non-cancer MINOCA and MI-CAD groups. Moreover, as has been shown in our multivariable models, lower hemoglobin levels worsen long-term prognosis in the whole group, but not in the population limited to patients with MINOCA. According to criteria similar to ours, anemia at baseline was found in approximately 40% of patients in the European Cancer Anemia Survey (37). This proportion increased up to 60–70% during either anticancer treatment or cancer progression, affecting the higher overall mortality risk (38). In our cancer patients with MINOCA, lower hemoglobin levels were associated with higher baseline troponin concentrations, suggesting the possibility of anemia-induced myocardial injury (16). As has been shown previously, active cancer should be considered as a secondary cause of troponinosis that is not associated with acute coronary syndrome (39, 40). Moreover, troponin elevation was linked with a higher mortality rate, especially in patients with lung cancer (41). We have also found that the ratio of troponin T to hemoglobin was significantly higher in both cancer populations when compared to the respective non-cancer groups. Our findings are one more argument for the adoption of a higher troponin cut-off value for MI in patients with cancer (39, 40). The relatively high proportion of patients with cancer-induced anemia, also visible in our cohort, may require blood transfusion or other available methods of treatment (erythropoietin or iron supplementation). In a propensity-matched analysis, Salisbury et al. have demonstrated that blood transfusion was associated with a lower risk of in-hospital mortality (42). In turn, a meta

analysis done by Chatterjee et al. indicates that a liberal blood transfusion strategy is associated with higher all-cause mortality when compared to a more restricted strategy, which might be associated with volume overload, increased thrombogenicity, impaired oxygen delivery, and a risk of infection (43).

## Limitations

Our study has several limitations. First, the analyzed cancer MINOCA group is relatively small. However, it represents a unique and comprehensively characterized cohort. Second, despite their obvious heterogeneity and applied various methods of anticancer treatment, due to the small sample size of patients with different types of cancer, a multivariable analysis had to be performed for all patients with cancer. Third, cardiac magnetic resonance and intracoronary imaging were not performed to confirm an alternative diagnosis including myocarditis (44, 45). Fourth, apart from death, we did not analyze other clinical outcomes, such as recurrent MI, ischemic stroke, or heart failure decompensation. Moreover, the fact of quitting smoking after the cancer diagnosis undoubtedly contributed to its underestimated self-reporting. Finally, we also did not perform specific coagulation tests that would determine the role of prothrombotic states involved in the etiology of MINOCA (8, 46, 47).

## CONCLUSIONS

Our findings provide evidence that active cancer in the whole cohort of patients with MI, overrepresented among the MINOCA population, is associated with extremely high long-term mortality. A multivariable approach indicates that an active

malignancy was independently associated with unfavorable long-term survival in the whole MI population as well as in patients with MINOCA.

Breast cancer and heart failure share several known clinical cardiovascular risk factors, including age, obesity, glucose dysregulation, cholesterol dysregulation, hypertension, atrial fibrillation and inflammation. However, to fully comprehend the complex interplay between risk of breast cancer and heart failure, factors attributed to both biological and social determinants of health must be explored in risk-assessment. There are several social factors that impede implementation of prevention strategies and treatment for breast cancer and heart failure prevention, including socioeconomic status, neighborhood disadvantage, food insecurity, access to healthcare, and social isolation. A comprehensive approach to prevention of both breast cancer and heart failure must include assessment for both traditional clinical risk factors and social determinants of health in patients to address root causes of lifestyle and modifiable risk factors. In this review, we examine clinical and social determinants of health in breast cancer and heart failure that are necessary to consider in the design and implementation of effective prevention strategies that altogether reduce the risk of both chronic diseases

**Keywords:** breast cancer, heart failure, risk factors, social determinants of health, reverse cardio-oncology

## INTRODUCTION

Cardiovascular disease (CVD) and cancer are the two leading causes of death in the United States in 2020 (1). Classically, the field of cardio-oncology has focused on the development of CVD directly from cardiotoxic effects of cancer biology and/or cancer therapies. But there is growing appreciation that the two diseases intersect at multiple levels, including shared clinical risk factors, shared social risk factors, and reverse cardio-oncology where CVD acts to promote cancer development (2). In this review, we focus specifically on the intersections between breast cancer

and heart failure (HF). Delving into anti-cancer therapies that cause cancer therapy-related cardiac dysfunction is beyond the scope of this review. Breast cancer remains the most common cancer in women, with one in eight women expected to develop breast cancer over the course of their lifetime (3). There have been notable improvements in survival rates for breast cancer due to earlier detection and advancements in treatment such that the 5-year relative survival rate from the mid-1970s to the present time has increased from 75 to 90% (4). Breast cancer survivors with a prior history of CVD who survive cancer for over 5 years are more likely to die of CVD, (5) and in breast cancer survivors age 66 years or older, CVD is often the primary cause of death (6). The lifetime risk of developing HF in women is even higher at one in five at age 40 and rises rapidly with increasing age (7, 8). The overall burden of HF continues to increase with the aging of the general population and with increases in HF risk factors such as obesity and diabetes. Thus, as women age they are at increased risk for both breast cancer and HF. Here we examine the shared pathophysiology and commonalities in clinical and social risk factors that lead to the high prevalence of both HF and breast cancer.

## Shared Clinical Risk Factors

Traditional clinical risk factors for HF in women are well established. Modifiable clinical HF risk factors that may also increase risk for breast cancer include diabetes, obesity, hypertension, hyperlipidemia, and atrial fibrillation (**Table 1**) (9). Inextricably linked with these risk factors are health behaviors such as tobacco use, alcohol use, physical inactivity, and an unhealthy diet. Prevention of risk factors (or primary prevention) and avoidance of poor health behaviors dramatically lower the risk of incident HF (10, 11). The causal pathways connecting these risk factors to increased risk of CVD and HF are well known (12–14). However, their association with increased risk of breast cancer is only starting to be appreciated (15). In this section, we summarize epidemiological and mechanistic evidence to better understand the relationship between some of the traditional cardiovascular risk factors and breast cancer.

## Obesity and Glucose Dysregulation

Of the common modifiable risk factors, diabetes and obesity have the strongest association with HF in women (16, 17). Multiple studies have also shown an increased risk of breast cancer in women with diabetes. In a meta-analysis of 39 independent risk estimates from observational epidemiological studies, women with diabetes had a 27% higher risk of developing breast cancer (summary relative risk [SRR] 1.27, 95% confidence interval [CI], 1.16 – 1.39) (18). In prospective studies, the risk of developing breast cancer remained 23% higher in women with diabetes (SRR 1.23 [95% CI, 1.12–1.35]). Part of the risk was mediated through concomitant obesity, but the risk of developing breast cancer remained 16% higher after adjusting for body mass index (BMI). Of note, the risk of breast cancer was not elevated in premenopausal women with diabetes or women with Type 1 diabetes. A more recent review of meta-analyses estimated a 20% greater risk of developing breast cancer in women with diabetes

**TABLE 1 |** Impact of modifiable heart failure risk factors that increase risk for breast cancer and potential underlying mechanisms.

Modifiable heart failure risk factors	Risk of breast cancer	Mechanisms
Diabetes	20% Increased Risk (19)	Hyperinsulinemia. Adipocyte Dysfunction. Hypoxia.
Obesity	25% Increased Risk (20)	Immune Cell Recruitment. Expression of Aromatase. Hyperleptinemia
Hypertension	15% Increased Risk (36)	Angiotensin II
Hyperlipidemia	9% Increased Risk (41)	27-hydroxycholesterol
Atrial Fibrillation	35% Increased Risk (47)	Reactive Oxygen Species

(19). Similarly, the risk of breast cancer is 25% higher in postmenopausal women with obesity (20). The risk of breast cancer increases by 10% for every 5 kg/m<sup>2</sup> higher BMI above 25 kg/m<sup>2</sup> in postmenopausal women (21). This association is strongest in estrogen receptor positive breast cancer (22). Obesity contributes to a chronic low-grade inflammation that can promote both carcinogenesis and atherosclerosis. Changes in the adipose tissue microenvironment can switch from anti-inflammatory to pro-inflammatory in obesity (23).

Glucose dysregulation is central to both disease processes and is integral to understanding the pathophysiology underlying this association. Both obesity and diabetes lead to adipocyte dysfunction, insulin resistance, and hyperglycemia (24, 25). The excess growth of adipose tissue results in hypoxia and expression of hypoxia-inducible factor 1a (HIF1a) (26). This results in adipocyte dysfunction, which promotes breast cancer growth through multiple interconnected pathways. First, adipocyte hypoxia results in release of chemokines such as monocyte chemoattractant protein 1 (MCP1), which recruits immune cells and creates a pro-inflammatory environment (27). Second, there is increased expression of aromatase, the rate-limiting enzyme in estrogen synthesis, which leads to higher levels of circulating estrogen (28). Higher levels of estrogen promote estrogen-responsive malignancies including breast cancer. Third, there is dysregulation of adipocyte endocrine function. In individuals with obesity, the central nervous system develops resistance to leptin, a hormone that limits appetite in healthy individuals (29). The subsequent hyperleptinemia promotes breast cancer initiation, growth, and progression by promoting cellular growth, inhibiting apoptosis, activating cellular adhesion and inflammatory immune cells (30). In contrast, in obesity there is reduced production of protective hormones such as adiponectin and ghrelin, both of which reduce breast cancer risk by inhibiting aromatase and other pathways associated with increased cancer cell proliferation (31, 32).

In combination with inflammatory cytokines, hypoxia, elevated estrogen, and altered milieu of adipokines, hyperinsulinemia and hyperglycemia lead to dysregulation of multiple metabolic pathways in not only breast cancer cells but also local stromal and immune cells (33). These triggers stimulate signaling cascades by activating receptor tyrosine kinases leading to activation of the phosphoinositide 3-kinase (PI3K)-AKT pathway and inhibition of the AMP-activated protein kinase (AMPK); favoring a shift toward aerobic glycolysis, glucose uptake, and cell proliferation in cancer, stromal, and immune cells (34, 35). These pathways also lead to aromatase activation in stromal cells and release of inflammatory cytokines from immune cells resulting in a positive feedback cycle and tumor progression (33).

### Hypertension

Hypertension is one of the most prevalent risk factors for both HF and breast cancer, especially as the population ages. Numerous observational studies have also evaluated the association of hypertension with risk of incident breast cancer. A large meta-analysis of 30 observational studies, including 11,643 cases of breast cancer, demonstrated a 15% higher risk of breast cancer in adults with hypertension (RR: 1.15; 95% CI 1.08 – 1.22) (36). In another meta-analysis of 13 prospective studies, the association between hypertension and breast cancer was again noted (RR: 1.07; 95% CI 0.84 – 1.35) (37). This was primarily driven by the association observed in postmenopausal women. Like diabetes, hypertension was not associated with increased risk of breast cancer among premenopausal women. Mechanisms behind hypertension and breast cancer risk are not well established. Since hypertension is often linked with diabetes and obesity, there are some shared pathways such as chronic inflammation as described above. One specific pathway that links both obesity and hypertension to breast cancer involves angiotensin II. While the renin-angiotensin system is well-known for its role in blood pressure and fluid regulation, it can be activated within dysregulated adipose tissue as well (38). Angiotensin II increases tumor angiogenesis in receptor-negative breast cancer and leads to activation of proinflammatory macrophages promoting tumor growth.

### Cholesterol Dysregulation

Dysregulation in cholesterol metabolism is another traditional cardiovascular risk factor that is associated with breast cancer. Some studies have demonstrated an association between high-density lipoprotein cholesterol (HDL-C) and breast cancer risk (39). In a study of 4,670 women with increased mammographic density, higher levels of HDL-C were associated with a 23% increased risk of breast cancer (40). While observational data have not consistently shown an association between low-density lipoprotein cholesterol (LDL-C) and breast cancer risk, a large mendelian randomization of > 400,000 participants found a significant association between genetic risk factors for lifelong elevated LDL-C and increased risk of estrogen receptor positive breast cancer (41). There is also evidence that higher dietary intake of cholesterol is associated with an increased risk of breast cancer in a non-linear fashion (42). However, it is

difficult to disentangle the effects of obesity and diabetes from hypercholesterolemia using observational data.

There is growing mechanistic evidence that links hypercholesterolemia with breast cancer. 27-hydroxycholesterol is an endogenous oxysterol that has activity as a selective estrogen receptor modulator (43). It is generated by the P450 enzyme sterol 27-hydroxylase CYP27A1 and is transported in conjunction with HDL-C and LDL-C. It has been shown to stimulate the growth of estrogen receptor positive breast cancer cells in human xenografts and animal models. Potential mechanisms include inhibition of tumor suppressor proteins, activation of growth factors, and immune dysregulation such as suppression of cytotoxic CD8+ T cells within tumors (44). More work is needed to better understand this pathway and how cholesterol lowering therapies such as statins may affect it. Current data do not show convincing evidence of statin therapy protecting against breast cancer development but there are multiple observational studies suggesting a benefit of lipophilic statins on breast cancer recurrence and mortality (45).

### Atrial Fibrillation

There is an association between atrial fibrillation (AF) and cancer, with inflammation contributing to the development of both in part through the production of reactive oxygen species. Elevation in C-reactive protein levels and increased NLRP3 inflammasome activation have also been reported in AF (46). Whether atrial fibrillation itself increases the risk of developing cancer requires further investigation. In a cohort study of 34,691 women followed for a median of 19 years, new-onset AF was found to be a significant risk factor for incident breast cancer after age-adjusted models (hazard ratio [HR], 1.35; 95% CI, 1.01–1.81;  $p < 0.04$ ). This risk was highest in the first 3 months after incident AF, but remained beyond 1 year (47). Atrial fibrillation may also be a marker for occult cancer. Patients with cancer have a higher prevalence of AF compared to those in the general population (48). Women with breast cancer diagnosis have a significantly higher incidence of AF, with increasing risk for those who present at a higher breast cancer stage. Incident AF in newly diagnosed breast cancer also increases 1-year CV mortality (49).

### Inflammation

As described above, immune dysregulation and inflammation are common final pathways that link traditional HF risk factors to breast cancer development. Obesity can lead to a chronic low-grade inflammation which leads to accumulation of pro-inflammatory adipose tissue macrophages, increased levels of aromatase, estrogen biosynthesis, and increased risk for estrogen-dependent breast cancer after menopause (28). Some inflammatory pathways are shared in HF and cancer pathogenesis. Pro-inflammatory cytokines such as tumor necrosis factor (TNF), interleukin (IL)-1B, IL-6, and IL-18 have been shown to play a role in left ventricular dysfunction and adverse remodeling (50, 51). Increased expression of these cytokines, especially IL-1B, is due to activation of the NLRP3 inflammasome (52). The Canakinumab Anti-Inflammatory Thrombosis Outcome Study (CANTOS) evaluated the effect

**TABLE 2 |** Common social risk factors between heart failure and breast cancer.

Social risk factor	Heart failure	Breast cancer	Potential solutions
Low socioeconomic status	<ul style="list-style-type: none"> <li>↑ Incidence of disease</li> <li>↑ Mortality after 90 days of discharge</li> <li>↓ Likely to be referred to subspecialist</li> <li>↑ Hospitalizations, readmissions, and mortality</li> </ul>	<ul style="list-style-type: none"> <li>↑ Incidence of disease</li> <li>↑ Aggressive premenopausal breast cancer</li> <li>↑ Stage of breast cancer diagnosis</li> <li>↑ Mortality</li> </ul>	<ul style="list-style-type: none"> <li>- Create a robust income safety net</li> <li>- Increase income benefits</li> <li>- Increase jobs/employment</li> <li>- Expand unemployment insurance</li> </ul>
Neighborhood disadvantage	<ul style="list-style-type: none"> <li>↑ Incidence of disease</li> <li>↓ Ejection fractions</li> <li>↑ Hospitalizations, readmissions, and mortality</li> </ul>	<ul style="list-style-type: none"> <li>↑ Stage of breast cancer diagnosis</li> <li>↑ Breast cancer mortality</li> </ul>	<ul style="list-style-type: none"> <li>- Create a robust income safety net</li> <li>- Increase affordable public housing; prioritize for homeless</li> <li>- Rental assistance</li> <li>- Investment in low-income communities</li> <li>- Investment in schools, early childhood education, and mentorship programs</li> <li>- Build affordable transportation</li> <li>- Partner with social services addressing homelessness</li> </ul>
Food insecurity	<ul style="list-style-type: none"> <li>- Frailty and deconditioning</li> <li>- Poor access to low-sodium diet</li> <li>- Obesity, diabetes, hypertension more prevalent</li> </ul>	<ul style="list-style-type: none"> <li>- Dietary fat linked to reduced breast cancer</li> <li>- Obesity, diabetes, hypertension more prevalent</li> </ul>	<ul style="list-style-type: none"> <li>- Create a robust income safety net</li> <li>- Address food deserts</li> <li>- Expand food benefits</li> <li>- Expand universal free meals to children</li> <li>- Partner with local food banks and fridges</li> </ul>
Poor access to healthcare	<ul style="list-style-type: none"> <li>- Lack of continuity care</li> <li>- Lack of subspecialty care</li> <li>↑ Medication costs</li> </ul>	<ul style="list-style-type: none"> <li>↓ Cancer screening</li> <li>↑ Delays in diagnosis and treatment of breast cancer</li> </ul>	<ul style="list-style-type: none"> <li>- Create a robust income safety net</li> <li>- Affordable healthcare</li> <li>- Universal healthcare</li> <li>- Partner with community health centers</li> <li>- Prioritize access in health services</li> </ul>
Social isolation	<ul style="list-style-type: none"> <li>↓ Physical and mental health</li> <li>↑ Hospitalizations, readmissions and mortality</li> </ul>	<ul style="list-style-type: none"> <li>↓ Physical and mental health</li> <li>↓ Survival</li> </ul>	<ul style="list-style-type: none"> <li>- Access to mental health services</li> <li>- Increase social workers on healthcare teams</li> <li>- Patient support groups</li> <li>- Partner with local programs for the elderly</li> </ul>

of canakinumab, a monoclonal antibody targeting interleukin-1B (IL-1B), on cardiovascular outcomes (53, 54). Canakinumab significantly reduced not only cardiovascular events and HF hospitalizations but incident lung cancer and decreased lung cancer-related death. While the trial did not have enough power to look at different cancer subtypes, breast cancer tumor cells have been shown to produce IL-1B, which promotes epithelial-to-mesenchymal transition, migration, and invasion of breast cancer cells (55). Animal models have shown reduction in breast cancer metastasis with IL-1B inhibition (55). Identification of these shared pathways may allow for targeted therapies for both breast cancer and HF.

## Shared Social Risk Factors

Poverty and inequality form the backbone of underlying social risk factors that contribute to social determinants of health (SDOH). These are primary concerns for healthcare providers who must consider community-level factors that influence health outcomes. Thriving in a society involves addressing a complex association between personal, environmental, economic, and social factors that impact overall health. There are multiple SDOH assessment tools which have been developed to comprehensively evaluate these outcomes. SDOH screening tools must be better integrated into healthcare delivery schema

in cardio-oncology. Several social risk factors derived from these tools are known to contribute to both cancer and HF, including socioeconomic status, neighborhood disadvantage, food insecurity, an inadequate healthcare system (lack of insurance, cost of medication), and social isolation (56, 57). These social issues have come to the forefront during the COVID-19 pandemic, where we have witnessed the selective effect of COVID-19 on disadvantaged communities. The pandemic has motivated a conversation to address these disparities in healthcare, which are deeply rooted in the structural inequities in our society. Potential mitigation strategies must be directed at multiple levels (Table 2). In this section, we summarize social risk factors that contribute to both breast cancer and HF.

## Socioeconomic Status

There is a known association between socioeconomic characteristics and risk for both breast cancer and HF. Across racial and ethnic groups, increasing socioeconomic status is inversely correlated with breast cancer incidence in population studies (58). Low socioeconomic status is associated with increased risk of aggressive premenopausal breast cancer, later stage of diagnosis, and poorer survival (56). Breast cancer's 3-year survival is significantly affected by level of education, district of residence and social class in childhood (59). Mortality

is significantly higher in non-Hispanic Black breast cancer patients than non-Hispanic white patients, across all ages (60). Cardiovascular health is also worse in Black individuals who have a higher prevalence of HF risk factors such as obesity, diabetes, and hypertension than non-Hispanic white individuals (61, 62). Black individuals have higher rates of HF hospitalization and age-adjusted HF-related CVD death rates than their White counterparts (63). When compared to White survivors of breast cancer, Black survivors have an elevated risk of cardiotoxicity-associated morbidity and mortality (64).

Socioeconomic factors also predict outcomes from HF admissions. Those patients with adverse social factors in a Medicare dataset were 3-fold as likely to die within 90 days of discharge for a HF hospitalization as those without any social risk factors (65). In a study from Sweden evaluating HF outcomes, lower socioeconomic status was directly associated with patients being less likely to have a subspecialist referral (66). This may in part be due to the financial burden of care for cancer patients which is even higher when superimposed with atherosclerotic CVD (a major risk factor for HF), leading to difficulty paying bills, buying medications, and seeking care (67).

There is a linear relationship between number of socioeconomic risk factors and higher risk of HF hospitalization, cardiovascular events, and mortality (66). Prevention focusing on modifiable clinical risk factors is difficult for patients without socioeconomic support and resources. A patient with income instability must prioritize housing, food, utilities, and other needs over healthy activities such as a moderate-intensity exercise routine. Lower socioeconomic status is associated with a significant increase in body mass index, smoking prevalence, and diabetes (68). Other major risk factors for HF including coronary artery disease and hypertension also vary widely with levels of adverse social factors (69). Due to these underlying risk factors, those patients from lower socio-economic classes have a higher prevalence of incident HF 5 years earlier than those from more affluent backgrounds (68).

### Neighborhood Disadvantage

Poor infrastructure and inadequate resources in low-income neighborhoods serve as barriers to healthcare. Housing insecurity, the role of public transportation, and travel costs may serve as physical impediments to access healthcare but have not been well studied. Geographic proximity and travel time to mammography facilities have not been shown to be associated with later stage breast cancer diagnosis (70). However, high census tract poverty (defined by the US census as  $\geq 20\%$  below poverty) and inner-city disadvantage have shown an association with risk of later stage breast cancer diagnosis (70, 71). In addition, concern for safety due to neighborhood violence or crime, lack of public spaces such as parks, and lack of exercise facilities can lead to a less active and more sedentary lifestyle. Obesity is highly correlated with neighborhood poverty (71), having both direct and indirect effects on breast cancer and HF. Stressors associated with poverty can cause a patient to turn to risky behaviors such as smoking, drinking, and drug use as coping mechanisms. High-income neighborhoods have

demonstrated lower stress, anxiety, rates of obesity, and fewer other comorbidities (72).

Neighborhood deprivation index includes four main components: wealth and income, education, occupation, and housing quality (73). Akwo and colleagues demonstrated that neighborhood deprivation predicts risk of incident HF beyond individual socioeconomic status and traditional cardiovascular risk factors in low-income populations (74). Residents living in deprived neighborhoods have lower ejection fractions, more severe HF symptoms and higher odds of hospitalization for HF (75). Thirty-day HF readmission and mortality rates also increase with neighborhood deprivation (76). Neighborhood socioeconomic status is also an important factor in cancer-specific survival disparities in Black and non-Hispanic Whites (77).

### Food Insecurity

Food insecurity is the lack of reliable access to nutritious food for healthy and active living, resulting in not having enough meals or cutting back on meals. It is a broad concept of adapting eating to social circumstances primarily driven by poverty, income instability, and neighborhood disadvantage. Food deserts are areas in primarily low-income neighborhoods where access to grocery stores that provide fresh fruits and vegetables is limited (78). This may also contribute to difficulty in adhering to a low-sodium diet for patients with HF when facing food insecurity. For patients with breast cancer and HF, food insecurity can have the potential to aggravate both conditions. Food insecurity and lack of healthy food is associated with HF risk factors and HF, but whether food insecurity and access to healthy food is associated with breast cancer requires further study.

One hypothesized mechanism for the association of SDOH and risk of HF is lack of access to healthy foods, more processed foods, and therefore higher dietary phosphate intake, which may increase circulating levels of inorganic phosphate and fibroblast growth factor 23 (FGF-23). FGF-23 has been correlated with increased myocardial fibrosis on cardiac MRI and a strong predictor of mortality and first HF hospitalization, especially in patients with HF with preserved ejection fraction (79). Further investigation is needed to understand the relationship between a high phosphate diet and breast cancer. Ultra-processed foods in diet have been associated with increased risks of overall and breast cancer (80). There may also be a possible link between lipids, higher HDL-C and apolipoprotein A1, and mammographic density which needs further study (40). A few studies have noted that dietary fat, n-3 PUFA, has an inverse link to breast cancer (81, 82).

Frailty and deterioration resulting from undernutrition has also been shown in patients with HF (83). Interventions such as the Supplemental Nutrition Assistance Program (SNAP), community partnerships through food pantries, school meals, and community fridges are needed to address food insecurity and health-related comorbidities.

### Healthcare System

There are well-documented disparities in breast cancer survival and HF by socioeconomic status, access to health insurance, and

preventive care. Lack of adequate health insurance leads to high out of pocket medical costs, inability to pay for medications, lack of a primary care physician to perform screening studies, and provide subspecialty referral. The difficulty in navigating screening and treatment for HF or cancer is exacerbated by poverty, lack of insurance, and not having an established continuity clinic. Other socioeconomic factors such as lower education, health literacy, and higher stress levels were associated with lower HF clinic use (84). Patients without health insurance often seek care at safety-net or federally funded hospitals and indigent care clinics. When unable to afford healthcare or medications, patients may need to make trade-offs between basic needs and treatments.

Prevention is a large component in the management of both HF and breast cancer. It has been demonstrated that decreased cancer screening rates are associated with delayed diagnosis and treatment and poorer health outcomes (56). In a study by Kurani and colleagues, 78,302 patients eligible for breast cancer screening living in rural areas were 24% less likely to obtain breast cancer screening than those living in the city. Those living in the most deprived census blocks were 49% less likely to obtain breast cancer screening (85). Interventions such as providing transportation and childcare assistance, providing free screening services, or distributing educational resources through community partnerships have proven to be cost-effective measures at improving quality and length of life by increasing cancer screening (86). As previously outlined, socioeconomic factors effect access to heart failure care and subspecialty clinics (66). Racial disparities also exist in admission for heart failure, referral for diagnostic tests, and administration of advanced heart failure therapies (87, 88).

### Social Isolation

Finally, the importance of social networks and connections for both breast cancer and HF patients has been well-established. High levels of social support have been shown to be protective for physical and mental health and quality of life (56, 89). In addition, several studies have demonstrated worse all-cause mortality and breast cancer mortality in patients without robust social support (90–92). These studies quantify social support based on both the number of people in the social network as well as the frequency of contact with friends/family following cancer diagnosis. In a study of 2,835 nurses from the Nurses' Health Study, participants that were socially isolated were twice as likely to die as those who were socially connected (90). Those with strong social support were also most likely to adhere to treatment regimens, access healthcare, and treatment options more effectively (93).

One prospective study of HF patients found that 6% of patients experienced severe social isolation; even after controlling for depression, these patients had >3.5 times increased risk of death 68% increased risk of hospitalization, and 57% increased risk of emergency department visits compared to those who did not report social isolation (94). In another study, loneliness was directly associated with more days hospitalized and more readmissions despite equivalent severity of HF (95).

### Mitigation Strategies

To address the underlying factors that promote both HF and breast cancer, a multi-faceted approach is needed that focuses on SDOH and in turn clinical risk factors (Table 2). A singular theme across all domains of SDOH is a need for a robust income safety net for low-income individuals. Creation of policies that focus SDOH will have a transformational effect on comorbidities that affect HF and breast cancer. Health legislation such as the Patient Protection and Affordable Care Act expanded health insurance, largely through Medicaid, to low-income individuals with cancer and at rates similar to those without cancer (96). This led to increased diagnosis of early-stage breast cancer; however, there was no evidence of increase in timely initiation of cancer treatment due to earlier diagnosis (97). Similarly, although more low-income HF patients were now insured, largely through Medicaid expansion, this did not improve quality of care or in-hospital outcomes in low-income patients with HF (98). These findings underscore a need for an all-encompassing approach, beyond expansion of health insurance, that addresses affordable housing, transportation, food insecurity, access to healthcare, and building social support networks. An intervention such as the Supplemental Nutrition Assistance Program (SNAP) serves as an example for mitigating adverse health outcomes in individuals with food insecurity (99). Working alongside health and social policy makers, community partners, and patients to develop comprehensive intervention strategies that address structural inequities are needed to broaden our view of how to improve health outcomes for breast cancer and HF.

### Reverse Cardio-Oncology

The newer concept whereby HF promotes cancer development is supported by both epidemiological and mechanistic data. In an initial case-control study, HF was associated with nearly 70% higher risk of incident cancer after adjusting for comorbidities (100). This association was present regardless of left ventricular ejection fraction. In a large population-based study of a Danish cohort, individuals with HF had a higher incidence of cancer across different age groups (101). Specifically, there was a 36% higher risk of breast cancer. In addition to incident cancer, two prospective cohort studies in early-stage breast cancer showed a 60% increased risk of recurrence in women who had an interim myocardial infarction (MI) (102). Baseline CVD risk factors, 10-year atherosclerotic CVD risk score, and natriuretic peptide concentrations are associated with increased risk of future cancer (103). Results from observational studies, however, can be biased due to increased surveillance in patients with HF and differences in treatment. Therefore, it is crucial to identify biological pathways that may explain this association.

Animal studies have provided important insights into the association between CVD and cancer. The initial hallmark study evaluated the effect of HF induced by a large anterior MI in mice prone to developing precancerous intestinal tumors (104). Mice with HF had significantly greater tumor growth. Tumor growth was associated with left ventricular dysfunction and myocardial scar. In their panel of candidate proteins, SerpinA3 consistently induced proliferative effects in the tumor via the Akt pathway. There have also been studies specifically evaluating the effect of

adverse cardiac remodeling in breast cancer models. In a mouse model of breast cancer, MI induced by coronary artery ligation led to 2-fold increase in tumor growth compared with controls (102). Analysis of the intra-tumoral immune cells showed an increase in monocytic myeloid-derived suppressor cells. These suppressor cells restricted infiltration of anti-tumor cytotoxic T cells, instead promoting pro-tumoral immunosuppressive T regulatory cells. These changes were in part mediated by epigenetic modification of monocytes in the bone marrow.

In a separate breast orthotopic cancer mouse model, pressure overload induced cardiac hypertrophy from transverse aortic constriction led to greater tumor growth and more metastases (105). Tumor growth correlated with the level of cardiac hypertrophy. The authors further identified increased messenger RNA expression of periostin in hypertrophied hearts and increased protein levels in serum. Depletion of periostin from the serum inhibited proliferation of cancer cells while addition of periostin promoted cancer cell proliferation in vitro. Periostin is an extracellular matrix protein that affects cancer cell proliferation, migration, and epithelial to mesenchymal transition. Interestingly, SerpinA3 was not elevated in this mouse

model. This may represent differences in early and late stages of cardiac remodeling and HF or mode of cardiac injury. These studies further support the paradigm of reverse cardio-oncology but also reinforce the need for additional studies to better delineate the different pathways that connect CVD to cancer, specifically HF to breast cancer. Greater understanding of the mechanisms would not only allow for targeted therapy but more importantly emphasize the importance of HF and cancer prevention through aggressive risk factor modification by both patients and clinicians.

## CONCLUSIONS

The interplay between risk factors associated with breast cancer and HF is very complex. Traditional cardiovascular risk factors, such as obesity, glucose dysregulation, hypertension, cholesterol dysregulation, atrial fibrillation and inflammation, are also closely linked with the development of breast cancer. HF itself has been shown to increase tumor growth and cancer development. Overarching social factors that lead

**FIGURE 1 |** Interconnected social and clinical risk factors, and mechanisms which link the development of breast cancer and heart failure.

to development of these cardiovascular risk factors, and in turn to breast cancer and HF, must simultaneously be addressed in order to comprehensively develop approaches for prevention of both chronic illnesses (Figure 1). Poverty and inequality are the root causes of several of these social risk factors, such as socioeconomic status, neighborhood disadvantage, food insecurity, an inadequate healthcare system, and social isolation. Implementation of prevention strategies must consider these social factors with equal importance

when addressing common risk factors between breast cancer and HF.

Cardiovasc. Med.* 9:916325. doi: 10.3389/fcvm.2022.916325

**Aim:** This study investigated the factors predicting survival and the recurrence of pericardial effusion (PE) requiring pericardiocentesis (PCC) in patients with cancer.

**Materials and Methods:** We analyzed the data of patients who underwent PCC for large PEs from 2010 to 2020 at The University of Texas MD Anderson Cancer Center. The time to the first recurrent PE requiring PCC was the interval from the index PCC with pericardial drain placement to first recurrent PE requiring drainage (either repeated PCC or a pericardial window). Univariate and multivariate Fine-Gray models accounting for the competing risk of death were used to identify predictors of recurrent PE requiring drainage. Cox regression models were used to identify predictors of death.

**Results:** The study cohort included 418 patients with index PCC and pericardial drain placement, of whom 65 (16%) had recurrent PEs requiring drainage. The cumulative incidences of recurrent PE requiring drainage at 12 and 60 months were 15.0% and 15.6%, respectively. Younger age, anti-inflammatory medication use, and solid tumors were associated with an increased risk of recurrence of PE requiring drainage, and that echocardiographic evidence of tamponade at presentation and receipt of immunotherapy were associated with a decreased risk of recurrence. Factors predicting poor survival included older age, malignant effusion on cytology, non-use of anti-inflammatory agents, non-lymphoma cancers and primary lung cancer.

**Conclusion:** Among cancer patients with large PEs requiring drainage, young patients with solid tumors were more likely to experience recurrence, while elderly patients and those with lung cancer, malignant PE cytology, and non-use of anti-inflammatory agents showed worse survival.

**Keywords:** malignant pericardial effusion, recurrence, pericardiocentesis, survival, cancer patients

## INTRODUCTION

Pericardial effusion (PE) is relatively common in cancer patients and is primarily caused by tumor invasion or disease treatment (1). Among cancer patients, malignant PE frequently occurs in those with advanced disease and is associated with worse outcomes (2, 3). The spectrum of malignant pericardial disease ranges from asymptomatic PE to hemodynamic instability in the setting of cardiac tamponade or constrictive physiology. Despite aggressive treatment, the prognosis of cancer patients with PE remains poor and is primarily dictated by the characteristics of the underlying disease (4). The treatment of PE attempts to correct hemodynamic instability and minimize interruptions in cancer therapy with the long-term goal to prevent effusion recurrence.

It is unknown which method of managing PE with imminent or recurrent tamponade is the most effective; however, pericardiocentesis (PCC) and surgical drainage (*via* a pericardiotomy or pericardial window) are widely used (5). The management of patients with PE and tamponade should be determined by the probability of recurrence of PE and expected survival time. Little information exists regarding the factors that may predict development of recurrent PE in these patients. The duration from the index PCC to first recurrence of PE requiring another drainage is also not well studied. Furthermore, the impact that recurrent PE has on the treatment and overall prognosis of cancer patients with PE is not known. Therefore, the aim of this study was to identify the factors predicting survival and recurrent PE requiring PCC in cancer patients.

## MATERIALS AND METHODS

We conducted a retrospective analysis of a cohort of cancer patients who underwent index PCC from 2010 to 2020 at The University of Texas MD Anderson Cancer Center and were listed in “MD Anderson’s Pericardiocentesis Cardiac Catheterization Lab Registry.” The study was approved by MD Anderson’s Institutional Review Board.

### Patient Population

All patient data including imaging data was obtained using retrospective chart review. We collected patients’ demographic and clinical data, including age, sex, type of malignancy, prior cancer therapy (chemotherapy, immunotherapy, stem cell transplantation, surgery, and radiation), laboratory values, and cancer stage at the time of the index procedure. We also documented the clinical symptoms, signs, and echocardiographic findings of patients presenting with PE. An echo-free space 2 cm or larger was indicative of a large PE while echocardiographic evidence of tamponade was defined by presence of chamber collapse, mitral and tricuspid valve inflow variation on Doppler images, and inferior vena cava size and respiratory variation (6). Computed tomography scans and echocardiograms were reviewed to detect primary or metastatic tumors involving the heart and described as “cardiac involvement by primary tumor or metastases. The effusion pathology and microbiology

results obtained at the time of PCC were also reviewed to determine the percentage of patients with ‘malignant effusion on cytology.’ Cancer groups were divided into solid and hematological malignancies and then further sub-classified into 7 major types, including lung; breast; colon and other gastrointestinal malignancies (such as esophageal, stomach, hepatic, and pancreatic malignancies); renal and genitourinary malignancies; other solid tumors; lymphomas; and leukemia and other hematological malignancies. Patients’ cancers, were stratified as “advanced” (stage III or IV) or “non-advanced” (stage I or II). Determinants of recurrent PE requiring drainage were reviewed. A recurrent PE requiring drainage was defined as an effusion that caused clinical signs or symptoms as well as showed echocardiographic evidence of tamponade, and required drainage (either a pericardial window or repeated PCC). Patients who underwent a pericardial window for the index PE were excluded from the study.

### Pericardiocentesis Procedure

Patients underwent primary percutaneous PCC, which, for therapeutic and/or diagnostic purposes, was guided by echocardiography, computed tomography, fluoroscopy, or combined echocardiography and fluoroscopy in the cardiac catheterization laboratory. Percutaneous PCC was performed using either the subcostal or the lateral/intercostal approach, whichever provided the shortest distance from the skin to the pericardial cavity and preferably lateral in the thrombocytopenic patients (7, 8). A pericardial drain was placed in each patient and was removed once the amount of drainage was less than 30 cc in a 24-h period or if the duration of the drain placement exceeded 7 days. Handheld bedside echocardiography was encouraged immediately prior to drain removal, but the decision to use it was left up to the treating physician. As a routine practice, formal echocardiography was performed prior to drain removal as well as at follow-up in the outpatient cardiology clinic at 4–6 weeks and at 3–6 months to assess for PE recurrence. Procedure failure was defined as failure to place the catheter in the pericardial space or the presence of less than 10 ml drainage during the initial procedure. Procedure complications were defined as cardiac death, cardiac perforation, pneumothorax, or bleeding requiring transfusion during or within a few days after the procedure, after ruling out other obvious causes of such events.

### Data Analysis

Continuous variables were described as means  $\pm$  standard deviations (SDs) or as medians with interquartile ranges (IQRs). Categorical variables were described as counts and percentages. The time to the first recurrent PE requiring drainage was defined as the time from the index PCC with pericardial drain placement to the first recurrent PE requiring drainage with either repeat PCC or a pericardial window. Patients without recurrent PE requiring drainage were censored at the time of death or last follow-up. The event of interest was recurrent PE requiring drainage with either repeat PCC or a pericardial window. Death without recurrent PE requiring drainage was considered as a competing risk event, an event that precludes the occurrence of the event of interest, recurrent PE (9). When a competing risk of

death exists, it may not be appropriate to simply censor patients who died before they had a chance to experience recurrent PE. Ignoring the competing risk could result in incorrect estimation of the risk of recurrent PE. Therefore, univariate and multivariate Fine-Gray models were used to assess the covariates' effects on the cumulative incidence of recurrent PE, accounting for death as a competing risk (10). Overall survival (OS) was defined as the time from the index PCC to death or last follow-up. Univariate and multivariate Cox regression models were used to identify risk factors associated with death. For model selection, the backward elimination method (for the Fine-Gray models) and stepwise selection method (for OS) were used. Subdistribution hazard ratios (sHRs) and 95% confidence intervals (CIs) were provided for Fine-Gray models and hazard ratios (HRs) and 95% CIs were provided for Cox regression models, as appropriate. *P*-values less than 0.05 were considered statistically significant. SAS version 9.4 (SAS Institute, Inc., Cary, North Carolina) was used for data analysis. Median follow up was determined using reverse Kaplan-Meier curve.

## RESULTS

### Patients' Baseline Characteristics

The cohort included 418 patients (mean age,  $53 \pm 16$  years) with an index PCC. The patients' baseline characteristics are summarized in **Table 1**.

Most patients had advanced cancers (stage III or IV). All patients had large PEs, and most presented with echocardiographic evidence of tamponade (95%). Eight percent of patients had imaging evidence of cardiac metastasis. Two-thirds of the patients had malignant effusion on cytologic examination. Anti-inflammatory agents were prescribed in 11.8% of patients.

### Follow-Up and Outcomes

The median follow-up time was 48 months (95% CI, 43–51 months), and the median OS duration was 3.9 months (**Figure 1**). Majority of patients (92%) reported improvement in symptoms after draining pericardial effusion. Among all the patients who had index PCC, the rates of procedure complications and procedure failure were very low (0.24% each); the single procedure complication was a cardiac perforation (**Table 2**). Recurrent PE requiring drainage occurred in 65 (15.6%) patients; in 63 (15%) of these patients, it occurred within 1 year of the index PCC (**Figure 2**). Three hundred thirty-eight (80.9%) patients died by the end of the follow-up period. Cumulative incidence plots showed a statistically significant increase in recurrence of pericardial effusion in young patients and with anti-inflammatory medication use (**Figure 3**).

### Factors Determining Recurrence of Pericardial Effusion Requiring Drainage

The covariates that affect the incidence of recurrent PE requiring drainage are shown in **Table 3**. Univariate Fine-Gray models with death as a competing risk identified younger age, higher

serum creatinine and hemoglobin levels, cardiac invasion by the tumor, and chemotherapy and surgery as the factors that have a significant increasing effect on the cumulative incidence of recurrent PE. The multivariate Fine-Gray model identified younger age, anti-inflammatory medication use, and solid malignancy as the factors with an increasing effect on the cumulative incidence of recurrent PE, while having echocardiographic evidence of tamponade at presentation and

receiving immunotherapy were associated with a decreasing effect on the cumulative incidence of recurrent PE.

## Factors Determining Survival

The predictors of death are shown in **Table 4**. Univariate Cox regression models identified that older age, malignant effusion on cytological examination, and primary lung cancer were associated with an increased risk of death. Stem cell transplant and primary lymphoma were associated with a decreased risk of death. The multivariate Cox model identified that malignant effusion on cytological examination, not using anti-inflammatory agents, and non-lymphoma malignancies were associated with an increased risk of death.

## DISCUSSION

In this study, we report on a cohort of 418 cancer patients presenting with PE treated with percutaneous PCC. Our study had several key findings. First, factors independently associated with an increasing effect on the cumulative incidence of recurrent PE requiring drainage included younger age, anti-inflammatory medication use, and solid tumors, whereas factors associated with a decreasing effect on the cumulative incidence of recurrent PE requiring drainage included having echocardiographic evidence of tamponade at presentation and receiving immunotherapy. Second, factors independently associated with poor OS included

older age, malignant effusion on cytology, non-use of anti-inflammatory agents, non-lymphoma cancers and primary lung cancer. Third, PEs can be successfully drained with a very low rate of complications. Lastly, only 16% of patients presented with recurrent PEs requiring drainage, and almost all occurred within the first year after the index PCC.

In our study, the most frequent tumors associated with PEs requiring drainage were lung cancers (30.4%), followed by lymphomas (14.6%), leukemias (13.4%), and breast cancers (10.3%). While some studies have reported a similar percentage of cancer patients with pericardial effusion having hematological malignancies (1), others have reported a relatively less prevalence (4). Since most of these studies have been single center, this difference in observation can be explained by different patient population in each center. Most patients had advanced malignancies. In about two-thirds of our patients, cytological analysis of the pericardial fluid was positive for malignant cells; this was an independent predictor of a poor prognosis. This finding is in line with previous studies showing that recurrent, malignant PE occurs more commonly in patients with previously identified cardiac involvement than in those without it (11–14). In our study, 95% patients had echocardiographic evidence of tamponade while 5% patient underwent PCC for various reasons including clinical signs and symptoms related to large pericardial effusion, to establish the diagnosis of cancer, and for cancer staging.

In a retrospective analysis of cancer patients whose cumulative incidence of recurrent PE was 26.1% at 2-year interval from their index PCC, the use of anti-inflammatory agents was linked to a lower rate of death and PE recurrence (15). Similarly, we found that not using anti-inflammatory agents was associated with poor OS. However, in contrast to that study, we found that the risk of recurrence was higher with the use of these agents. This may represent a selection bias for the use of such therapies in patients who are generally thought to have

a higher risk of recurrence or may reflect the use of anti-inflammatory agents to facilitate pericardial drain removal in patients requiring longer periods of pericardial drainage. This selection bias can also be due to use of such agents in patients with progressive primary cancer with increased tendency to develop recurrent effusions. Also, using anti-inflammatory agents in patients with hemorrhagic effusion can potentially lead to increased bleeding in pericardial space and increased recurrence risk (16, 17). In another study, rate of recurrence of pericardial effusion requiring pericardiocentesis was reduced from 23 to 11% with catheter drainage for 3–5 days as compared to not using an indwelling catheter (1). This alone was sufficient to reduce the risk of recurrence considerably and our data suggests that use of anti-inflammatory medications in the immediate peri-procedure phase (first week) might be hindering the beneficial effect of extended catheter drainage and mechanically induced adhesions.

Previous studies have shown conflicting evidence regarding the association between malignant cells in the pericardial fluid and poor outcomes in cancer patients (18–20). Our results indicate an association between malignant cells in the pericardial fluid and worse OS in cancer patients. Results from our analysis showed that patients with solid tumors had poor survival if they had malignant cells in the pericardial fluid; however, the outcomes did not differ for other cancer types when stratified by the results of cytological analysis.

In our study, almost all patients who developed recurrent PE developed it within 1 year after the index PCC. Specifically, the PE recurrence rate was only 15% in the first year after the index PCC and increased to only 16% after 5 years. This rate is lower than that reported previously (13). The low recurrence rate in our study can be explained by the close monitoring of the pericardial drain output, the standardized approach used for drain removal (based on 24-h drain output), and the encouraged use of echocardiography prior to drain removal. Among the patients who had recurrent PEs requiring drainage, the OS and recurrence rates did not differ between the patients who had had a pericardial window versus those who were treated percutaneously. This finding establishes the safety and utility of PCC in high-risk patients with cancer who present with PE recurrence (21, 22).

No randomized studies have compared the percutaneous drainage of PEs to the surgical drainage of PEs. Retrospective

studies have shown that surgical drainage can reduce recurrence but increase the risk of peri-procedure complications (23). The American Heart Association and American College of Cardiology offer no guidelines on the management of pericardial disease. According to the 2015 European Society of Cardiology guidelines for pericardial disease, the treatment of cardiac tamponade related to a malignant PE effusion is a class I indication for PCC. Surgical pericardiotomy is indicated when PCC cannot be performed (class IIa; level of evidence B), but the surgical procedure may be associated with a higher rate of complications than PCC is and may not result in better outcomes (24). Guidelines for the treatment of PE recurrence do not exist. The choice between catheter-based and surgical drainage is usually made by a multidisciplinary team that includes the patient's oncologist, cardiologist, and thoracic surgical team, and it should be individualized to each patient and consider the patient's preference. In both percutaneous and PE treatment, the subcostal and intercostal (apical/lateral) approaches are similarly efficacious. Whether these approaches are successful depends primarily on the characteristics and location of the effusion, the stability of the patient, and various laboratory and clinical characteristics, including the presence of a chest wall tumor, the patient's history of chest wall radiation or abdominal surgery, or an apical loculation of the pericardial effusion (25–27). Our study found no difference in survival or PE recurrence between the 2 percutaneous approaches.

The safety of PCC was well demonstrated in our study in which the rates of procedure failure and complications were very low (0.24% each). One systematic review showed that the incidences of recurrent PE after isolated pericardiocentesis, PCC with extended catheter drainage, pericardial sclerosis, and percutaneous balloon pericardiotomy were 38.3%, 12.1%, 10.8%, and 10.3%, respectively (14). Despite being associated with a relatively high rate of recurrence, PCC continues to be a very attractive option for high-risk cancer patients. Some prefer to use surgical pericardial windows rather than PCC as the initial PE treatment in cancer patients owing to the high rate of cancer invasion into the pericardium and the high recurrence rate of PE; however, pericardial windows may be suboptimal for these patients because such patients tend to be frail and because the use of pericardial windows may delay their recovery from surgery and general anesthesia and thus affect their cancer treatment schedule. The high success rate of PCC and its low complication

and recurrence rates in our large cohort of cancer patients shows the value of the percutaneous procedure, with continued drainage over a few days, as a first line therapy for large PEs in these patients. That PCC is associated with no significant delay in cancer treatment (surgery, chemotherapy, immunotherapy, or radiation therapy) further supports its use in this population (28).

As suggested in our study, routine surveillance echocardiograms done at 3–6 weeks and at 4–6 months after index PCC can help determine which patients are more likely to develop recurrent effusions and may warrant closer monitoring and subsequent surveillance echocardiograms. In the current study, the median OS duration for cancer patients requiring

PCC was 3.9 months (95% CI, 3–4.9 months). Although this duration is a little higher than that reported previously (15), the finding reiterates that PE requiring drainage is a poor prognostic marker in patients with cancer because it is indicative of advanced malignancy.

## Study Limitations

Because this study was a retrospective chart review, it was subject to selection bias, as decisions regarding the procedure, entry site, imaging guidance, drainage duration, and use of anti-inflammatory agents were individualized to each patient and at the discretion of the treating physician. The use of standardized

protocols for PCC at our institution as well as protocols for surveillance imaging prior to and after drain removal may have helped counter the bias to some extent. Initial performance status data were not obtained, and symptomatic improvement and quality-of-life metrics were not quantified or collected owing to the urgent/emergent nature of the procedure, though immediate symptom relief was often recognized. Outcomes of patients with recurrent pericardial effusion managed with therapies such as pericardial window or instillation of intra-pericardial sclerosing agents were not included in our study. Since this study included patients from ‘Cardiac Catheterization Lab’ database, a direct comparison cannot be made with patients who had malignancy

but did not meet inclusion criteria for the study and hence did not undergo PCC.

## CONCLUSION

Pericardiocentesis is an attractive option in cancer patients with large pericardial effusion with acceptable recurrence rate. Aggressive cancers (younger patients with solid malignancy) have an increased risk of recurrent PE within the first year from the initial PCC, while elderly patients with lung cancer and malignant PE cytology have worse survival. Cancer patients

requiring treatment with immunotherapy appear less likely to require additional PCC. Future studies will continue to refine and align cancer and cardiovascular care to benefit patients facing this double jeopardy.

## DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by MD Anderson Institutional Review Board. The ethics committee waived the requirement of written informed consent for participation.

## AUTHOR CONTRIBUTIONS

TA, CI, AD, and EM contributed to the conception and design of the study. JS, EK, and NP organized the database. JS performed

the statistical analysis. TA, JL-M, and PK wrote the first draft of the manuscript. SY, SH, MC, KM, AV, AD, CI, and SS wrote sections of the manuscript. All authors contributed to manuscript revision, read, and approved the submitted version.

## FUNDING

NP was supported by the NIH/NCI 1P01CA261669-01, the Cancer Prevention & Research Institute of Texas (RP200670), the Sabin Family Foundation Fellowship, and the MD Anderson Department of Internal Medicine Research Development Award. AD was supported in part by the Ting Tsung and Wei Fong Chao Distinguished Chair. SH received funding and act as a consultant for TerSera Therapeutics, LLC.

Song Y, Wang Y, Wang Z, Xu C, Dou J and Jiang T (2022) Comparing Clinical Outcomes on Oncology Patients With Severe Aortic Stenosis Undergoing Transcatheter Aortic Valve Implantation: A Systematic Review and Meta-Analysis. *Front. Cardiovasc. Med.* 9:890082. doi: 10.3389/fcvm.2022.890082

**Objective:** To compare the clinical outcomes of cancer and non-cancer patients with severe aortic stenosis (AS) after transcatheter aortic valve implantation (TAVI).

**Methods:** A computer-based search in PubMed, EMBase, The Cochrane Library, CBM, CNKI, and Wanfang databases from their date of inception to October 2021, together with reference screening, was performed to identify eligible clinical trials. Two reviewers independently screened the articles, extracted data, and evaluated their quality. Review Manager 5.3 and Stata 12.0 software were used for meta-analysis.

**Results:** The selected 11 cohort studies contained 182,645 patients, including 36,283 patients with cancer and 146,362 patients without cancer. The results of the meta-analysis showed that the 30-day mortality [OR = 0.68, 95%CI (0.63,0.74),  $I^2=0$ ,  $P < 0.00001$ ] of patients with cancer in the AS group was lower than those in the non-cancer group; 1-year mortality [OR = 1.49, 95%CI(1.19,1.88),  $I^2=58\%$ ,  $P = 0.0006$ ] and late mortality [OR = 1.52, 95%CI(1.26,1.84),  $I^2=55\%$ ,  $P < 0.0001$ ] of patients with cancer in the AS group was higher than those in the non-cancer group. The results of the meta-analysis showed that the stroke [OR = 0.77, 95%CI (0.72, 0.82),  $I^2=0$ ,  $P < 0.00001$ ] and the acute kidney injury [OR = 0.78, 95%CI (0.68, 0.90),  $I^2=77\%$ ,  $P = 0.0005$ ] of patients with cancer in the AS group was lower than those in the non-cancer group. The results of the meta-analysis showed no statistical difference in cardiovascular mortality, bleeding events, myocardial infarction, vascular complication, and device success rate.

**Conclusion:** It is more effective and safer in patients with cancer with severe AS who were undergoing TAVI. However, compared with patients with no cancer, this is still high in terms of long-term mortality, and further study of the role of TAVI in patients with cancer with AS is necessary.

## INTRODUCTION

With the uptrend of aging in the world, the morbidity of valvular disease in the elderly is increasing, in which AS has gradually become the most common valvular heart disease in the elderly. The main manifestations of AS are angina pectoris, syncope, dyspnea, and even sudden death. The effect of conservative treatment is not good, though it can relieve the clinical symptoms, the aortic valve function cannot recover, affecting the quality of life of patients. The results of the American population survey showed that the incidence of severe valvular disease in the elderly is 2.5%, including 13.3% in people over 75 years old. European surveys showed that the incidence of AS in the population is 4%, and 2% in the elderly population (1). In addition, not only the incidence of AS is increasing year by year, but also the prognosis is very poor. Once the symptoms or cardiac function decrease, the mortality increases sharply. If only conservative treatment is performed, the 2-year fatality rate is 50% to 60%. Therefore, active intervention is needed.

Since transcatheter aortic valve implantation (TAVI) appeared in 2002, it has become a vital treatment of choice for patients with severe AS (2, 3). TAVI is sending the artificial valve to the aortic valve area to replace the aortic valve to perform its functions. TAVI indications listed in the 2017 European Valve Management guidelines: symptomatic patients with severe AS who are not suitable for surgery (I, B); or patients with higher surgical risk are defined as STS score or Euro SCORE II  $\geq 4\%$ , or other risk factors, such as weakness, porcelain aorta, and chest radiotherapy, especially suitable for elderly patients with femoral artery approach (I, B). The indications for TAVI listed in the 2017 American Valve Management guidelines are symptomatic in severe patients with AS with surgical taboos or high risk and expected survival of more than 12 months (I, A); surgical risk severe AS patients (II, a).

The TAVI has quickly developed all over the world because of its small trauma and rapid recovery. At present, more than 300,000 cases have been completed in more than 60 countries (4, 5). Among them, cancer patients with severe AS become a special group of valvular disease because of tumor recurrence, metastasis, and other characteristics. However, related research on the clinical efficacy and safety of TAVI in patients with cancer with severe AS is limited and the conclusion is still controversial. Therefore, the purpose of this study is to systematically evaluate the early and medium-term clinical efficacy of TAVI in patients with severe AS with cancer.

## DATA AND METHODS

### Data Sources

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) statement was followed. A comprehensive literature search was performed through the PubMed, Embase, The Cochrane Library, CBM, CNKI, and Wanfang databases from their establishment to October 2021 using the following terms: “transcatheter aortic valve implantation,” “transcatheter aortic valve replacement,” “TAVI,” “TAVR,” “neoplasm,” “malignancy,” “cancer,” and “tumor” with

no restrictions on language. Reference lists of reviewed articles were screened to identify further relevant studies. When outcomes reporting was incomplete, the study authors were contacted for further information.

### Study Selection

Inclusion criteria were as follows: studies performed in patients with severe AS and cancer; study design comparing patients with cancer undergoing TAVI to patients without cancer undergoing TAVI; reporting the 30-day, 1-year, and late mortality. In the meta-analysis, we included patients with an active history of cancer.

### Eligibility Criteria

All studies were included based on the following inclusion criteria: (1) the study enrolled patients with AS with cancer; (2) the study intervention was TAVI with no restrictions on the valve style (balloon- or self-expandable valve) or delivery route; (3) the study compared clinical outcomes of patients with cancer to patients without cancer undergoing TAVI; (4) the study design was randomized controlled trials (RCT) or cohort studies.

Studies will be excluded if one of the following conditions is met: (1) the type of study was case-control studies, case reports, conference abstracts, reviews, comments, or editorials were excluded; and (2) a significant amount of research data was missing or not available.

### Study Selection and Data Extraction

The first author (YS) and the second author (YW) independently screened titles and abstracts of all identified records to exclude unrelated studies based on inclusion/exclusion criteria. After that, relevant studies and full articles were reviewed to further determine their suitability. Disagreements were resolved by discussions with a third reviewer (ZW) or by consensus.

### Clinical Endpoints

The primary outcome is all-cause mortality in 30-days, 1-year, and late mortality. The second outcome included myocardial infarction (MI), stroke, bleeding events, major or minor vascular complications, new permanent pacemaker implantation, acute kidney injury (AKI), and device success.

### Risk of Bias and Statistical Analysis

The Cochrane Collaboration's tool for assessing the risk of bias was utilized to assess the risk of bias in RCTs, including: (1) sequence generation; (2) allocation concealment; (3) blinding of participants and personnel; (4) blinding of outcome assessment; (5) incomplete outcome data; (6) selective outcome reporting; and (7) other bias. Moreover, the Newcastle-Ottawa Scale (NOS) (6) was used to assess the quality of cohort studies consisting of three factors: patient selection, comparability of the study groups, and the assessment of outcomes.

Categorical variables were reported as percentages, and continuous variables were presented as the mean  $\pm$  SD. We reported clinical outcomes and their respective effect size in all

included studies using odds ratios (ORs), with corresponding 95% confidence intervals (CIs).

Heterogeneity assessments were performed using  $\chi^2$ -based Q statistics and  $I^2$  tests. If  $P > 0.10$  and  $I^2 \leq 50\%$ , there was no statistical heterogeneity among results; if  $P < 0.10$  and  $I^2 > 50\%$ , there was a considered significant heterogeneity. All the results were performed using the random effect model. Subgroup analyses were also performed to find more potential information based on a different type of event. The likelihood of publication bias was assessed directly through the funnel plots, evaluated using an Egger's test. All analyses were performed using Review Manager 5.3 and Stata 12.0 software.

## RESULTS

### Baseline Demographic and Quality Assessment

A total of 1,140 potentially eligible studies were identified in our initial search, and 11 clinical studies met the inclusion criteria (5, 7–16) (**Figure 1**). A total of 182,645 patients were enrolled, including 36,283 patients in the cancer group and 146,362 patients in the non-cancer group. The basic information of these studies is in **Table 1**. There were significant statistical differences in the mean Society of Thoracic Surgeons score (STS score) [ $WMD = -0.76$ , 95%CI (-1.14, -0.37),  $I^2 = 70\%$ ,  $P =$

## Clinical Outcomes

### All-Cause Mortality

For all-cause mortality, subgroup analysis of included studies illustrated that there were significant differences among them. At 30-day mortality, 11 studies were enrolled (5, 7–16) and the random effect model showed that the cancer group had a significantly lower all-cause mortality than the non-cancer group

[ $OR = 0.68$ , 95%CI (0.63, 0.74),  $I^2 = 0$ ,  $P < 0.00001$ ]. However, cancer group had higher mortality than non-cancer group at 1-year (5, 7, 8, 11, 13–16) [ $OR = 1.49$ , 95%CI (1.19, 1.88),  $I^2 = 58\%$ ,  $P = 0.0006$ ] and late (5, 7, 8, 11, 13–16) [ $OR = 1.52$ , 95%CI (1.26, 1.84),  $I^2 = 55\%$ ,  $P < 0.0001$ ] (Figure 2).

### Cardiovascular Mortality

There was no significant statistical difference in cardiovascular mortality [ $OR = 1$ , 95%CI (0.83, 1.19),  $I^2 = 2\%$ ,  $P = 0.96$ ] between the two groups.

## Stroke

There were 10 studies (5, 7, 9–16) included and the meta-analysis showed that the patients with cancer were associated with a significantly lower rate of stroke than the non-cancer group [OR = 0.77, 95%CI (0.72, 0.82),  $I^2 = 0$ ,  $P < 0.00001$ ] (Figure 3A).

## Acute Kidney Injury

There were 7 studies (5, 7, 9, 10, 12, 13, 16) included and the meta-analysis showed that the patients with cancer were associated with a significantly lower rate of acute kidney injury (AKI) than the non-cancer group [OR = 0.78, 95%CI (0.68, 0.90),  $I^2 = 77\%$ ,  $P = 0.0005$ ] (Figure 3B).

## New Permanent Pacemaker

There were 8 studies (5, 9–11, 13–16) included and the meta-analysis showed that the patients with cancer were associated with a significantly higher success rate of new permanent pacemakers than the non-cancer group [OR = 1.11, 95%CI (1.03, 1.19),  $I^2 = 30\%$ ,  $P = 0.005$ ] (Figure 3C).

## Other Clinical Outcomes

There were no differences in any bleeding events [OR = 1.13, 95%CI (0.82, 1.56),  $I^2 = 84\%$ ,  $P = 0.45$ ], device success [OR = 1.14, 95%CI (0.63, 2.08),  $I^2 = 56\%$ ,  $P = 0.66$ ], myocardial infarction [OR = 0.92, 95%CI (0.30, 2.86),  $I^2 = 57\%$ ,  $P = 0.88$ ], major vascular complications [OR = 1.16, 95%CI (0.76, 1.78),  $I^2 = 14\%$ ,  $P = 0.48$ ], and minor vascular complications [OR = 0.72, 95%CI (0.35, 1.48),  $I^2 = 76\%$ ,  $P = 0.38$ ] between two groups.

## Publication Bias

The funnel plot analysis and the Egger's test were used to examine the publication bias of included studies. Funnel plot analysis of all results did not show significant asymmetry. The Egger's test showed no significant publication bias in 30-day all-cause mortality ( $P = 0.819$ ), 1-year all-cause mortality ( $P = 0.668$ ), late and all-cause mortality ( $P = 0.806$ ), stroke ( $P = 0.509$ ), new permanent pacemaker implantation ( $P = 0.991$ ), and AKI ( $P = 0.589$ ) (Figure 4).

## DISCUSSION

Patients with severe AS with tumors are a special group of valvular diseases (2, 3). The choice of intervention for AS is a matter of concern, because of their operation or drug intolerance, which will affect the choice of best anti-tumor therapy (5). The European Society of Cardiology (European Society of Cardiology, ESC) proposed that we can release the left heart failure caused by antineoplastic therapy by reducing the afterload of the left ventricle (17); while for AS, the afterload can be effectively reduced only through aortic valve intervention. The main clinical intervention methods for aortic valve include balloon valvuloplasty, aortic valve replacement (Surgical Aortic Valve Replacement, SAVR), and TAVI. It has been proved that balloon valvuloplasty cannot improve the survival rate of patients with AS, and has many complications (18, 19). Although SAVR can improve the survival rate of patients with cancer with severe AS (20), it will have higher perioperative mortality compared to

non-cancer patients with AS because of its intolerance to open surgery (21). The revolutionary innovation of TAVI provides a great opportunity for the treatment of severe AS, which may also be the best treatment for patients with AS with cancer. TAVI has the advantages of minimal trauma and rapid recovery, which not only reduces the risk of bleeding and infection after SAVR but also avoids the interruption of perioperative antineoplastic therapy (21, 22).

The purpose of this study was to compare the difference in mortality between cancer and patients without cancer with severe AS in TAVI. The results of the meta-analysis showed that there was no significant difference in the cardiovascular mortality, any bleeding events, vascular complications, and myocardial infarction between the two groups, indicating that in patients undergoing TAVI, mortality was mainly affected by non-cardiac factors (23), such as cancer progression or metastasis. Meta-analysis showed that  $I^2$  was  $>50\%$  in 1-year and late all-cause mortality, but much  $<75\%$ , while Egger test  $p$ -values were  $>0.05$ , which concluded that there was no significant heterogeneity. In the 30-day, the all-cause mortality in the cancer group was lower than the non-cancer group, while in the 1-year and late all-cause mortality, the mortality in the cancer group was higher than that. Maybe in short-term treatment, TAVI relieves patients' cardiac symptoms and plays a positive role in anti-tumor treatment (24), so the short-term survival rate is increased. In addition to this, the 2017 American Valve Management guidelines state that the indications for TAVI include a life expectancy of more than 12 months after treatment to correct AS (25). Patients with cancer who choose to undergo TAVI are generally younger and have a lower risk than patients without cancer, and they also have a higher survival rate in the short term. But compared with patients without cancer, even though the patients in the cancer group are younger and have lower STS scores, the long-term survival rate decreases due to the continuous influence of tumor factors (tumor progression, metastasis, recurrence, etc.).

This study also found that in the complications after TAVI, there were significant differences in the incidence of stroke, acute kidney injury, and new permanent pacemaker. The meta-analysis showed that in the cancer group, there was a lower rate of stroke and AKI than in the non-cancer group. Stroke is a common complication after TAVI and can be classified as perioperative (within 30 days after TAVI or during hospitalization), early period (between 30 days and 1 year after TAVI), and late period (more than 1 year) depending on the time of occurrence (26, 27). A stroke occurs in the perioperative period mainly due to debris dislodgement generated during TAVI, which includes aortic wall components, atherosclerotic tissue, and valves, and it may also be triggered by damage to the aortic wall caused by the procedure (28, 29); stroke occurs in the early and late periods mainly due to valve-related turbulence, vessel wall rupture, metal frame exposure, and other procedure-related factors (30). On the one hand, patients in the cancer group had lower STS and Euro II scores than those in the non-cancer group, we believe that patients in the oncology group had better vascular conditions than those in the non-oncology group and were less likely to have a stroke due to debris from vessel wall damage or poor valve placement. The ESC/EACTS,

**FIGURE 3 |** The forest plots of (A) stroke, (B) AKI and (C) new permanent pacemaker.

AHA/ACC, and ESC/EAPCI committees have not reached a consensus on the choice of anticoagulation regimen after TAVI (31–33), but they all choose the appropriate anticoagulation

therapy based on clinical experience and the patient's actual situation. Although patients in the cancer group are more likely to have hypercoagulable blood due to their tumors, routine

anticoagulation after TAVI can reduce the risk. On the other hand, the meta-analysis showed that there is no statistically significant difference between the two groups in any bleeding events, which also demonstrates the effectiveness of either anticoagulation regimen in reducing blood hypercoagulability. While the large number of contrast media needed for an operation may cause acute renal function damage after the operation, we can see from the data that the age and STS scores of patients in the cancer group are lower than those in the non-cancer group. The lower score indicates that the patients in this group have fewer risk factors than the non-cancer group, which leads to a lower incidence of acute kidney injury after TAVI. The conduction block is also a common complication after TAVI, so 13% of patients after TAVI need permanent pacemakers to improve survival. In this study, there were statistical differences in the new permanent pacemaker implantation between the two groups. The cancer group had a higher implantation rate; however, data were collected in this meta-analysis without access to the preoperative ECG results

of patients, including whether they had preoperative right bundle branch block (RBBB) or atrioventricular block (34), so we considered that the higher rate of permanent pacemaker implantation in the cancer group compared to the non-cancer group may be due to the possibility that they had a high degree of atrioventricular block or were unable to remove the temporary pacemaker after TAVI.

The strength of this meta-analysis is the inclusion of 11 articles including 182,645 patients, adequately comparing the differences between cancer and non-cancer groups in terms of various outcome indicators. This study also has the following limitations: (1) no published randomized controlled trials were included, meaning the study is only included in the cohort study for analysis, which may cause certain bias; (2) the study does not carry out a cost-benefit analysis, such as hospital stay, hospitalization costs, etc., so we cannot clarify the related economic burden of TAVI and cancer treatment; (3) due to the limitations of the follow-up time included in the study, the study only analyzed the outcome

indexes in the early and medium-term by Meta, and failed to explore the longer-term prognosis of TAVI in patients with severe AS with cancer; and (4) data were collected in this meta-analysis without access to the preoperative ECG results.

## CONCLUSION

In conclusion, it is effective and safe to apply TAVI to the treatment of severe AS in patients with cancer, but compared with patients without cancer, the long-term mortality rate is still higher. More large samples and multicenter studies are needed in the future.

**Background:** Immune checkpoint inhibitors (ICIs) are widely used in lung cancer management. However, myocarditis, which is a rare, yet potentially severe adverse-related event associated with ICIs, could be under-reported.

**Objectives:** This study is aimed to prospectively evaluate the cumulative incidence rate of myocarditis, through systematic screening, among patients receiving ICIs for lung cancer.

**Methods:** All patients who received the first administration of ICIs for non-small cell (NSCLC) and small cell lung cancer (SCLC), between May and November 2020, in the pulmonary department of Bordeaux University Hospital, were included. Echocardiography (ECG), troponin-I, and natriuretic peptide dosages before ICIs' first administration and before each infusion were recorded. ECG and magnetic resonance imaging (MRI) were done additionally, in case of at least three times increase in troponin levels, ECG modifications, and the onset of cardiovascular symptoms. Second, if possible, coronarography than endomyocardial biopsy was assessed. The primary outcome was defined as ICIs related to myocarditis onset, while secondary outcomes included other cardiovascular events, disease-free, and overall survival.

**Results:** During the period of interest, 99 patients received their first infusion of ICIs for lung cancer (mean age  $64 \pm 9$  years; 52 men, 67% with adenocarcinoma). Three cases of myocarditis without major adverse cardiac events (MACEs) occurred (two definite and one possible), and the mean duration between the first ICIs' administration and myocarditis onset was  $144 \pm 3$  days. Median disease-free survival and overall survival were 169 [102; 233] days and 209 [147; 249] days, respectively.

**Conclusion:** In our study, systematic screening of myocarditis associated with ICIs leads to a more frequent incidence and a later onset than previously reported. None of them

were severe. Additional prospective evidence is needed before we could adopt routine cardiac screening in unselected patients starting ICIs; however, these data shed new light on the risk of myocarditis associated with ICIs administration.

**Keywords:** myocarditis, screening, immune checkpoint inhibitors, lung cancer, early diagnosis

## INTRODUCTION

Immune checkpoint inhibitors (ICIs) have substantially improved clinical outcomes in multiple cancer types, such as lung cancer (1). In France, there are currently four approved ICIs in lung cancer, which are as follows: nivolumab, pembrolizumab, (both anti-programmed death-1, PD-1), atezolizumab, and durvalumab (both anti-programmed death ligand-1, PD-L1). The indications for their use in lung cancer treatment continue to expand and are often considered the first-line therapy (2). Unfortunately, these agents may induce a wide spectrum of immune-related adverse events (irAEs) by enhancing immune responses in non-target organs (3), including the cardiovascular system. While myocarditis is considered uncommon toxicity of ICIs with incidence varying from 0.01 to 1% (2). However, it is likely that myocarditis is under-reported, owing to an absence of systematic monitoring and coding mechanisms for cardiac events in immunotherapy trials. Moreover, myocarditis related to ICIs has been described to have a fulminant course, with a fatality rate of 30–50% (2). A meta-analysis of the incidence of immune-related adverse effects in patients treated for advanced non-small cell lung cancer (NSCLC) identified that myocarditis affects 0.5% of the whole population (3). Additionally, myocarditis has been reported to be differentially associated with available ICIs. For example, a combination of pembrolizumab and ipilimumab has shown a higher reporting of myocarditis as compared to one ICI alone or in combination with chemotherapy (4, 5). Although, myocarditis can also occur with immunotherapy administered alone (6). IrAEs may occur secondary to the inhibition of immune checkpoints leading to local and systemic auto-immune responses (CD4+ and CD8+ T cells recruitment along with macrophages infiltrate), which attack myocytes and cardiac conduction tissue that cause myocarditis (7).

Until now, the reported median time of the onset of myocarditis from the first ICIs' infusion ranges from 34 [21; 75] to 65 [2; 454] days (8). Since cardiac monitoring (e.g., ECG or troponin) is not routinely performed, in most immunotherapy trials or clinical practice, the true incidence of myocarditis remains still unknown. The diagnosis of myocarditis can be based on appropriate investigations as recommended by the European Society of Cardiology Guidelines (9). Interestingly, the clinical presentation of myocarditis ranges on a spectrum of mild-to-severe diseases from an asymptomatic increment in cardiac biomarkers to severe decompensation with end-organ damage, as suggested by clinical practice guidelines for the management

of irAEs (10). Therefore, the need for increasing awareness to suspect, diagnose, and treat ICI-related myocarditis is pivotal in lung cancer patients who receive ICI treatment.

Hence, the aim of this study was to prospectively evaluate (1) the incidence of myocarditis associated with ICIs administration and (2) the frequency of other major cardiovascular events, such as ischemic heart disease or heart failure, in stages IIIB–IV lung cancer patients.

## MATERIALS AND METHODS

### Study Design

All adult patients who initiated ICI treatment for stages IIIB–IV lung cancer between 1 May 2020 and 1 November 2020, in the pulmonary department of Bordeaux University Hospital, were included. All participants provided informed written consent. All patients who did not receive the first administration of ICI were excluded.

### Sample Size

The cumulative incidence rate of myocarditis associated with ICIs' administration varies from 0.01 to 1% (2). The hypothesis is that the event is under-reported. Based on previous work, we had anticipated a cumulative incidence rate of 2%. For an  $\alpha$ -error of 5% and a  $\beta$ -error of 10%, the number of patients required was 92. In order to take into account missing data or withdrawals of consent, a total of 98 patients needed to be included.

### Ethical Approval and Consent to Participate

The study protocol was approved by the Ethics Committee of CHU Bordeaux (France) and registered with the following number CHUBX2020RE0275. This work complies with the protection of personal health data and the protection of privacy with the framework of application provided by article 65-2 of the amended Data Protection Act and the general data protection regulations. All subjects provided informed written consent. All authors provided consent to publication.

### Data Collected

The following data were collected: demographic characteristics, smoking history, pre-existing cardiovascular diseases (coronary artery disease, arrhythmia, conduction abnormalities, and heart failure), lung cancer type [NSCLC and small lung cancer (SCLC)], grading [stages IIIB and IV, according to the 7th American Joint Commission on Cancer Tumor Node Metastasis (AJCC TNM) classification], ICI regimens, a combination of ICIs and chemotherapy, number of lines, pre-existing auto-immune diseases, and other immune side effects during treatment. We used The Strengthening the Reporting of Observational studies

**Abbreviations:** C-MRI, cardiac magnetic resonance imaging; ECG, electrocardiogram; ICIs, immune checkpoint inhibitors; irAEs, immune-related adverse event; TTE, trans-thoracic echocardiography; MACEs, major adverse cardiovascular events.

in Epidemiology (STROBE) reporting guidelines in our study (**Supplementary Data 1**).

## Myocarditis Suspicion

Baseline troponin and natriuretic peptide levels, ECG, and transthoracic echocardiography (TTE) were performed before the first ICI infusion to evaluate possible changes from baseline, e.g., changes in left ventricular ejection fraction (LVEF), diastolic function, new wall motion abnormalities, or pericardial effusion. Prior to ICI's administration, levels of biomarkers (troponin-I and natriuretic peptide) and ECG measurements were undertaken. Possible myocarditis was suspected, in case of any 1 of the following adverse events: new cardiovascular symptoms or at least 3 times increase in the levels of biomarkers beyond the level prior to ICI's administration, or any of the following ECG changes: new prolongation of the PR interval, atrioventricular block, ventricular arrhythmias, frequent premature ventricular complexes, ST depression, or diffuse T-wave inversions.

In the presence of an adverse event, additional scans were performed, which are as follows: TTE, cardiac magnetic resonance imaging (C-MRI), and coronarography. C-MRI was assessed with T2-weighted imaging, late gadolinium enhancement (LGE), extracellular volume fraction, and T1 and T2 mapping.

For the C-MRI diagnosis of myocarditis, the Lake Louise Criteria were used in our study, which states that if (2, 11) both myocardial edema and non-ischemic myocardial injury are identified on the C-MRI, it is highly suggestive of myocarditis.

## Myocarditis Diagnosis

Any one of the following criteria is used to diagnose myocarditis in a clinical setting, the presence of two major criteria having the best diagnostic value:

- Myocardial edema: Indicated by abnormal findings in T2 mapping or T2-weighted images.
- Non-ischemic myocardial injury: Ascertained by abnormal findings on T1 mapping, LGE, or extracellular volume fraction.

Additional supportive criteria (below) can be suggestive of myocarditis, however, in the absence of the aforementioned two criteria, they cannot be considered definitively diagnostic of myocarditis.

- Pericarditis: Indicated by either pericardial effusion or abnormal late gadolinium enhancement/T2 or T1 findings in the pericardium.
- Left ventricular systolic dysfunction: Indicated by regional or global wall motion abnormalities.

Coronary angiography was performed to rule out significant coronary artery disease. Then, endomyocardial biopsies were performed when possible and guided according to C-MRI abnormalities. The myocardial tissue was evaluated using the histological Dallas criteria, which require two main components: inflammatory infiltrate and myocardial necrosis (12). If myocarditis was suspected, it was categorized as

definite/probable/possible per consensus-based definition (13). Finally, treatments for myocarditis were decided according to international recommendations (2).

## Statistical Analysis

Data are provided as mean or *n* (%), as appropriate. A value of  $p \leq 0.05$  was considered statistically significant. All analyses were performed using Graph Pad Prism<sup>®</sup> statistical software.

## RESULTS

Between 1 May 2020 and 1 November 2020, 99 patients (52% men, mean age:  $64 \pm 9$  years) received the first administration of ICIs (**Figure 1**). In total, 38% of patients had pre-existing cardiovascular diseases and 15% suffered from pre-existing systolic or diastolic dysfunction. In addition, 6% of patients had positive troponin before starting treatment among whom, two patients had pre-existing stable ischemic heart disease and 1 presented tight aortic stenosis. The majority of the patients (66%) had adenocarcinoma (**Table 1**) and 67% were being treated with a combination of ICIs and chemotherapy, while 61% received first-line treatment. In total, 72% of patients received Pembrolizumab (**Table 2**).

Myocarditis was diagnosed in three patients during the 6-month follow-up (two definite and one possible, **Table 3**), indicating a cumulative incidence rate of 3%. All of them were asymptomatic. Troponin serum increment was seen for all three patients: 75.0 ng/l in the first case, 20.8 ng/l in the second case, and 202.0 ng/l in the third case. None of them had elevated troponin levels prior to ICIs. The mean duration between the first ICI administration and the onset of myocarditis was  $144 \pm 3$  days (147 days for the first and the second cases; 141 days for the third case). Grade 1 skin toxicity (irAE) was seen between the first and second infusions for one patient with myocarditis (patient 2); however, no pre-existing auto-immune disease was previously reported (**Table 3**). No ECG abnormalities were seen, and TTE revealed preserved LVEF for all patients. We were able to distinguish myocarditis from myocardial ischemia or myocardial infarction with early systematic coronary angiography.

The first patient had an asymptomatic elevation of cardiac biomarkers. C-MRI showed myocardial edema in T2 mapping and LGE in a non-coronary distribution (**Figure 2**). Endomyocardial biopsies were performed according to C-MRI abnormalities and found non-specific edema. This patient was classified as having definite myocarditis because of increased cardiac biomarkers, positive C-MRI, and negative coronary angiography (13). The second patient was classified as possible myocarditis because of asymptomatic elevation of cardiac biomarkers, with negative C-MRI and angiography for coronary artery disease (13). In addition, the third case was classified as having definite myocarditis because of asymptomatic elevation of cardiac biomarkers, positive C-MRI but negative angiography for coronary artery disease (**Table 3**) (13).

All three patients received corticosteroids as recommended (10, 14, 15), intravenous methylprednisolone, at a dosage of 1 mg/kg/day for the first patient, and oral prednisone, at a dosage

of 1 mg/kg/day, with no additional immunosuppressant drugs for the remaining patients. The treatments administered were in line with the American Society of Clinical Oncology (ASCO) clinical practice guidelines for irAEs, and troponin monitoring was also done (10). All three patients had mild myocarditis and recovered without complications. No major adverse cardiac events (MACEs), e.g., cardiovascular death, cardiac arrest, cardiogenic shock, and hemodynamically significant complete heart block requiring a pacemaker, were noted.

Considering the non-severe presentation and the absence of alternative choice, ICIs rechallenge was performed in the first and second cases, after the normalization of troponin level. In the first case, nivolumab was administered 124 days after myocarditis and continued due to the absence of a recurrence. In the second case, pembrolizumab was re-administrated, 71 days after myocarditis and recurrence occurred 42 days (three infusions) after rechallenge. The recurrence was detected by ECG changes (*de novo* left ventricular block) and serum troponin increment,

while C-MRI was normal. An endomyocardial biopsy was not performed because of a negative benefit-risk balance. Diagnosis of myocarditis was retained in view of ECG normalization under corticosteroid. No rechallenge was performed for the third patient.

After a 6-month follow-up, median disease-free survival and overall survival were 169 [102; 233] and 209 [147; 249] days, respectively. Mortality did not increase among patients with myocarditis at the end of follow-up ( $p = 0.29$ ; not shown).

For one patient, due to the increased serum troponin levels, coronary angiography was performed and it confirmed an underlying coronary artery disease, which was treated with angioplasty. The patient had not previously reported pre-existing cardiovascular disease; however, several cardiovascular risk factors (current smoking, age >50 years) were noted. Finally, systematic TTE before ICIs' first administration allowed us to detect eight cases of unknown systolic or diastolic dysfunction, of which one had LVEF between 40 and 50%, leading to

**TABLE 1 |** Patients' characteristics at inclusion.

Patients' characteristics		Whole cohort N = 99 (%)
General	Mean age (years)	64
	Male gender	51 (52%)
	Risk factor	
Risk factor	Smoking

a specific treatment; while the remaining seven had diastolic heart failure. Additionally, concerning the five patients with positive troponin before starting treatment, two patients had known stable ischemic heart disease and one patient had severe unknown aortic stenosis without surgical indication. The two last patients had a spontaneous normalization of troponin levels.

## DISCUSSION

In our prospective, hospital-based real-life cohort study, the screening of myocarditis was systematically assessed in 99

**TABLE 2 |** Patients' follow-up.

		Whole cohort N = 99(%)
ICI regimens	Pembrolizumab	71 (72%)
	Nivolumab	7 (7%)
	Atezolizumab	8 (8%)
	Durvalumab	11 (11%)
	Other	2 (2%)

	Combinaison	66 (67%)
Line of treatment	1st line	60 (61%)
	2nd line	33 (33%)
	≥3rd line	6 (6%)
Myocarditis		3 (3%)
Follow-up	Median follow-up (days)	209 [147 ; 249]
	Mortality rate	28 (28%)

ICI, Immune checkpoint inhibitors.

patients with lung cancer (stages IIIB–IV), receiving ICIs treatment. A 3% cumulative incidence rate of myocarditis was seen during a 6-month follow-up. All cases of myocarditis were mild and without MACEs. No increase in mortality was observed among patients with myocarditis. Finally, myocarditis occurred later than described in previous studies, i.e., the mean time of the onset between the first ICIs' administration and myocarditis was  $144 \pm 3$  days.

No specific clinical characteristics were identified with myocarditis onset; the three cases were different, in terms of histological cancer type, ICIs regimens, combination regimen, and line number. None of the cases had an underlying auto-immune disease. The first case had a history of coronary artery disease without heart failure and the second had a history of valve disease, without associated heart failure.

In addition, the incidence of myocarditis (3%) was higher than previously reported, range of 0.06–1.14% (2), which could perhaps be explained by the rigorous systematic monitoring and subsequent early detection of myocarditis. Systematic monitoring to detect myocarditis is not routinely performed in patients receiving ICI; which might lead to its under-reporting. While the incidence of myocarditis was high (3%); however, the cases were mild and did not affect mortality. This finding was contrary to the previous reporting of a fatality rate of 30–50%, associated with myocarditis due to ICIs treatment (2). The lack of myocarditis-related mortality in our study could perhaps be due to the compliance of the patients with monotherapy, e.g., a large safety database suggests that myocarditis occurs more frequently and severely with the combination of ipilimumab and nivolumab when compared to monotherapy (5). Another hypothesis could be that systematic screening leads to earlier detection of myocarditis.

**TABLE 3 |** Description of myocarditis cases.

	1st patient	2nd patient	3rd patient

Recurrence yes/no	No	Yes	-

ECG, electrocardiogram; ICI, Immune checkpoint inhibitors; TTE, Transthoracic echocardiogram; LVEF, Left ventricular ejection fraction; Cardiac-MRI, Cardiac Magnetic Resonance Imaging.

This in turn allowed a prompt withdrawal of ICIs and initiation of corticosteroid treatment (intra-venous or oral) to avoid a fulminant course (16). Moreover, myocarditis had a later onset than previously observed in other studies (8, 16),

which further underscores the need for prompt and rigorous systematic detection.

We also noticed a trend of better survival among patients who had myocarditis, suggesting a strong immune response. These

results correspond to the findings in the meta-analysis from Hussaini et al. (17) which state that immunotherapy has better efficacy in patients who developed irAEs in different cancers, such as lung cancer.

Besides, after troponin normalization under corticosteroid therapy and in the absence of therapeutic alternatives, rechallenge (8, 10) was considered in the first two cases, with a recurrence of mild myocarditis for the second case, but not for the first one.

Interestingly, all myocarditis presented a normal LVEF in TTEs. C-MRI was normal for one of the cases, and an endomyocardial biopsy was performed only once. Normal results are frequently seen in the early phase of the disease (7), with normal C-MRI being reported in almost 70% of patients (2). In conclusion, ICI-related myocarditis is a complex disease that bears resemblance to many other acute cardiac syndromes. Its diagnosis is difficult as it is based on a combination of different non-pathognomonic parameters, such as biomarkers (troponin, natriuretic, peptides), imaging (ECG, TTE, and C-MRI), and procedures (endomyocardial biopsy and coronary angiography). However, given the high incidence (3%) observed in this study, it is recommended to perform systemic screenings until more definitive data become available (18). C-MRI and endomyocardial biopsies are not available in all medical centers and due to their invasive nature might be unsuitable for asymptomatic patients. Our study indicates that while TTE does not help in the early diagnosis of myocarditis, it is relevant for screening other cardiovascular events. In fact, pre-therapeutic TTE detected 8 cases of heart failure and 3 cases of valve diseases. Of note, even if the first manifestations of myocarditis can be serious cardiac complications, e.g., ventricular arrhythmias and atrioventricular block, the LVEF is often preserved (5, 8, 16). For example, in a study by Mahmood et al. (18) 51% of patients with ICIs associated with myocarditis had a normal LVEF. In addition, in 38% of myocarditis patients, a normal LVEF was seen despite the development of MACEs.

Finally, smokers are at risk of lung cancer and atherosclerosis (19) making them a particularly vulnerable population for MACEs. In a large study, 66% of patients with cancer ( $n = 60,676$ ) also presented with an acute coronary syndrome; and the most prevalent cancers were lymphoma (19%) and lung cancer (18.3%) (20). Contrastingly, in a more specific study by van-Herk-Sukel et al. (21) patients with lung cancer ( $N = 3,717$ ) did not show a higher risk of developing myocardial infarction when compared with cancer-free controls. In our study, only 1 patient with cardiovascular risk factors had an elevation of troponin level linked to coronary artery disease and died a few months after diagnosis. However, cardiovascular co-morbidities (heart failure, myocardial infarction, and cardiac arrhythmias), which have been seen with low survival, in a study of 95,167 lung cancer patients, must be detected as earliest as possible (22).

## Strengths and Clinical Perspectives

To our knowledge, this is the largest published prospective study of ICI-associated myocarditis among patients with lung cancer. While no specific clinical characteristics were identified with myocarditis onset, our study does outline the advantages of using an early and sustained systematic screening strategy for

detecting myocarditis, when treating lung cancer patients with ICIs. The rigorous screening allowed for the early diagnosis and management of three cases of mild myocarditis and by extension could lead to a reduction in mortality.

## Study Limitations

This study has several important limitations, such as the small number of patients; therefore, we could not compare overall survival and progression-free survival depending on myocarditis occurrence. Our study was also monocentric with a possible center effect, in particular, for C-MRI and endomyocardial biopsy access. While the probability of an over-diagnosis should be considered with any screening test; however, in our study there was only 1 troponin increment (leading to angioplasty).

## CONCLUSION

This study outlines the usefulness of early monitoring for myocarditis in patients with lung cancer being treated with ICIs. Early monitoring is especially helpful in cases with non-specific symptoms and would help in decreasing the risk of fulminant progression of myocarditis. However, larger patient cohorts will be needed to estimate the true incidence of clinically meaningful immune-related cardiac events/myocarditis and importantly evaluate potential predictors to define higher-risk subgroups and refine screening and management strategies. Although improved detection and management of immune-related cardiovascular events are important, additional prospective evidence is needed before we can adopt routine cardiac screening in unselected patients starting ICI therapy.

# Cardiovascular Outcomes in the Patients With Colorectal Cancer: A Multi-Registry-Based Cohort Study of 197,699 Cases in the Real World

Shilong Zhang<sup>1</sup>, Yan Wang<sup>1</sup>, Pengfei Zhang<sup>1</sup>, Luoyan Ai<sup>1</sup> and Tianshu Liu<sup>1,2\*</sup>

<sup>1</sup> Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China, <sup>2</sup> Centre for Evidence-Based Medicine, Fudan University, Shanghai, China

**Purpose:** We aimed to investigate the mortality patterns and quantitatively assess the risks of cardiovascular death (CVD) in patients with colorectal cancer (CRC). We also established a competing-risk model to predict the probability of CVD for patients with CRC.

**Patients and Methods:** Patients with CRC who diagnosed between 2007 and 2015 in the Surveillance, Epidemiology, and End Results (SEER) database were included in the present study. The cumulative incidence function (CIF) was used for CVD and other causes of death, and Gray's test was used to determine the subgroup difference in CIF. The Fine-Gray proportional subdistribution hazards model was used for identifying independent risk factors for CVD. A novel competing-risk model was established to evaluate the probability of CVD for patients with CRC. The performance of the nomogram was measured by concordance index (C-index), calibration curve, decision curve analysis (DCA), and risk stratification.

**Results:** After a median follow-up of 37.00 months, 79,455 deaths occurred, of whom 56,185 (70.71%) succumbed to CRC and 23,270 (29.29%) patients died due to non-CRC, among which CVD accounted for 9,702 (41.69%), being the major cause of non-cancer deaths. The 1-, 3-, and 5-year cumulative rates for CVD were 12.20, 24.25, and 30.51%, respectively. In multivariate analysis, age, race, marital status, tumor size, tumor stage, advanced stage, surgery, and chemotherapy were independent risk factors of CVD among patients with CRC. The nomogram was well calibrated and had good discriminative ability, with a c-index of 0.719 (95% CI, 0.738–0.742) in the training cohort and 0.719 (95% CI, 0.622–0.668) in the validation cohort. DCA demonstrated that nomogram produced more benefit within wide ranges of threshold probabilities for 1-, 3-, and 5-year CVD, respectively.

**Conclusion:** This study was the first to analyze the CIF and risk factors for CVD among CRC based on a competing-risk model. We have also built the first 1-, 3-, and 5-year competing nomogram for predicting CVD. This nomogram had excellent performance and could help clinicians to provide individualized management in clinical practice.

## INTRODUCTION

Colorectal cancer (CRC), a common gastrointestinal cancer, is ranked as one of the three most common cancers worldwide, with 1,147,950 new cases and 53,200 deaths estimated in 2020 (1). The life expectancy of patients with CRC has considerably improved due to early diagnosis and treatment (2, 3). Therefore, increasing mortality burden is not derived from cancer but from non-cancer causes. However, the political risk of non-cancer mortality is an objective existence, but it hasn't caused plenty of attention in academia.

In the past decade, cardiovascular death (CVD) has been regarded as one of the most common late complications of cancer therapy (4, 5). Indeed, the introduction of novel chemotherapeutic or immunotherapeutic drugs has brought considerable survival benefits for patients with advanced tumors (6). Unfortunately, these agents can cause a series of adverse events in clinical practice (7–10), mostly due to the induced overactivation of immunity or even direct killing of non-target organs, including the heart (11, 12). Therefore, it is an emerging issue that warrants increased awareness and investigation by cardiologists, oncologists, and immunologists.

Despite multiple studies showing how chemotherapeutic and immunotherapeutic drugs may contribute to the increased risk of CVD among cancer survivors, studies that focus on the cardiovascular outcomes in patients with CRC remain scarce. A prior descriptive analysis of Surveillance, Epidemiology, and End Results (SEER) data reported that patients with CRC were associated with an increased risk of CVD within 1 year of diagnosis. Although this analysis highlights the frequency of CVD among CRC survivors (13), it has mainly focused on CVD using the standard Cox proportional hazards regression approach. This conventional method might lead to unreliable results when competing events are present (14). Competing risks usually exist in the field of medicine, which may sway the occurrence of endpoint events. In addition, they would become particularly critical in terms of the elderly population or long prognosis (15). Thus, competing risks is certainly worth taking into consideration when investigating the CVD of patients with CRC, which would give a clearer picture of CVD risks that these patients would confront.

In the present study, we aimed to perform a population-based analysis of a cohort of patients with CRC between 2007 and 2015 in the SEER database to identify the risk factors for CVD among patients with CRC, including those within different subgroups. Since competitive events exist when analyzing CVD through Cox regression model (16), we used a competitive risk model when working for this type of data and objective of study. We comprehensively assessed the risks of CVD among more than 42,000 patients with CRC. Based on these results, we built and internally validated a competing-risk model to evaluate the probabilities of CVD for patients with CRC. Our findings can help clinicians adopt accurate risk stratification, weigh the advantages and disadvantages of therapies, and help with the cure of disease,

improve the prognosis, and raise the quality of life for patients with CRC.

## MATERIALS AND METHODS

### Data Source and Study Cohort

The present study was a retrospective analysis of a cohort of patients with CRC that strictly followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) specifications (17). The data used in this study were taken from 18 SEER registries via the SEER\*Stat software (2017 submission). The 18 SEER registries with additional treatment fields that were used in this study provided detailed data about demographic and clinicopathological characteristics, treatment protocols, and follow-up.

### Study Population and Variables

This study included cases from the 18 SEER registries with CRC, which were proved by pathologic diagnosis. We selected the patients with CRC using the following topography codes: C18.0, C18.2, C18.3, C18.4, C18.5, C18.6, C18.7, C18.8, 18.9, C19.9, and C20.9. The dawn of tyrosine kinase inhibitors, 2007, was selected as a year of insurance that was accessible in the SEER database when investigating the role of socioeconomic factors in CVD (18). The eligible patients were selected using the following inclusion criteria: (1) diagnosed with CRC as the primary and only tumor; (2) diagnosed between 2007 and 2015; and (3) had active follow-up information and defined causes of mortalities. Then, the following information was obtained for each patient: year of diagnosis, age, sex, race, tumor stage, histological grade, tumor site, marital status, insurance status, surgery, radiotherapy, chemotherapy, survival months, and causes of death. Patients with missing data about any of above information were excluded.

### Outcomes

Cardiovascular death was the primary endpoint and was measured as the time from the date of diagnosis of CRC to death due to CVD (19). As recorded in the SEER database, CVD has six causes of death, namely, disease of heart, hypertension without heart disease, cerebrovascular disease, atherosclerosis, aortic aneurysm and dissection, and other diseases of arteries, arterioles, and capillaries (20). The non-CVD was defined from other causes and was considered as competing events against CVD. Patients who survived until the last follow-up or who were lost to follow-up before the end of the observation period were regarded as censored observations.

### Statistical Analysis

The difference of baseline characteristics between subgroups were compared with  $\chi^2$ . Cumulative incidence function (CIF) was calculated to evaluate the probabilities of each event at 1-, 3-, and 5-year. Subgroup analyses were performed based on patient's characteristics, and respective curves for CIF were produced. The difference in CIF were determined through Gray's test (21). Fine and Gray's subdistribution

proportional hazards model was performed for identifying the independent risk factors for CVD among patients with CRC (22). Moreover, based on Fine-Gray's model, a novel competing-risk model was developed to predict the probabilities of CVD at 1-, 3-, 5-year for patients with CRC. We used the concordance index (C-index) to measure discriminative performance of the model, and the consistency was measured using a calibration curve (18). Decision curve analysis (DCA) was performed to visually investigate the clinical utilities and net benefits of this model (23, 24). The packages *cmprsk*, *survival*, *mstate*, *rms*, *pec*, and *riskRegression* in the R software (version 3.2.5) were used to establish and validate the nomogram.  $p < 0.05$  in two-sided tests were statistically significant.

## RESULTS

### Patient Selections and Baseline Characteristics

Our study extracted 197,699 eligible patients diagnosed with CRC between 2007 and 2015 in the SEER program. The baseline characteristics of the whole study cohort are presented in **Table 1**. A larger proportion of patients were aged above 65 years (1,776, 65.7%), male (102,669, 51.9%), white (156,015, 78.9%), married (111,210, 56.3%), and insured (165,937, 83.9%). Most patients were diagnosed with grade II (69.6%), followed by grade III (16.8%), grade I (10.9%), and grade IV (2.8%) CRC. The distribution of SEER stage was as follows: 77,655 (39.3%) had localized stage, 81,662 (41.3%) had regional stage, and 38,382 (19.4%) had distant stage. A total of 179,100 (90.6%) patients were treated with surgery, 81,946 (41.4%) patients were treated with chemotherapy, and only 28,737 (14.5%) patients were treated with radiotherapy.

### Cumulative Incidence Function Survival Analysis

The median follow-up of the whole cohort was 37 months (IQR: 17.00–119.00). In total, 79,455 patients died during the follow-up, of whom 56,185 (70.71%) succumbed to CRC and 23,270 (29.29%) died due to non-CRC, among which CVD accounted for 9,702 (41.69%), being the major cause of non-cancer deaths (**Table 1**). In consideration of competing risks (death from other causes), we further performed cumulative incidence analysis in the whole cohort (**Table 2**). Overall, the 1-, 3-, and 5-year CIF of death due to CRC were 1.63, 3.16, and 4.71%, respectively. The 1-, 3-, and 5-year CIF of CVD were 12.20, 24.25, and 30.51%, respectively, while the 1-, 3-, and 5-year CIF of non-CVD were 1.93, 4.13, and 4.77%, respectively (**Table 2**). Furthermore, the CIF of CVD were significantly decreased in recent years (**Figure 1** and **Table 2**).

In the subsequent subgroup analyses stratified by patient characteristics (**Table 2**), we found that a high CVD primarily occurred in patients aged  $\geq 65$  years (**Figure 2A**) whose race was White (**Figure 2C**); were unmarried (**Figure 2D**); had any Medicaid (**Figure 2E**); who had right tumors (**Figure 2F**), small tumor size (**Figure 2G**), and I-II grade of tumor (**Figure 2H**); had localized SEER stage (**Figure 2I**); and were not treated with surgery (**Figure 2J**), radiotherapy (**Figure 2K**), or chemotherapy (**Figure 2L**). In addition, no significant difference in CVD was found in sex subgroup analyses (**Figure 2B**).

### Risk Factors for Cardiovascular Death Among Patients With Colorectal Cancer in the Training Cohort

As shown in **Table 3**, patients with CRC in the whole cohort were randomized into the training ( $n = 138,391$ ) and validation cohort ( $n = 59,308$ ) at a ratio of 7:3. The baseline characteristics between the two cohorts were well balanced. Furthermore, the

**FIGURE 2 |** Cumulative incidence estimates of CVD among patients with CRC according to (A) Age; (B) Sex; (C) Race; (D) Marital status; (E) Insurance status; (F) Tumor site; (G) Tumor size; (H) Grade; (I) SEER stage; (J) Surgery; (K) Radiotherapy; (L) and Chemotherapy. A solid line represents cause-specific death, while a dotted line represents other causes of death. Death from CVD was indicated as 1; death from CRC was indicated as 2; and death from non-CVD was indicated as 3.

sdHR, subdistribution hazard ratio; CI, confidence interval; Other, American Indian/Alaska Native/Asian/Pacific Islander; NOS, not otherwise specified; SEER, Surveillance, Epidemiology, and End Results; CRC, colorectal cancer; CVD, cardiovascular death.

CIF of CVD remained comparable between the two cohorts ( $p = 0.57$ ). To identify the independent risk factors for CVD in the training cohort, we conducted the univariate and multivariate Fine-Gray hazard model analysis. The univariate analysis showed

that CVD was significantly associated with age, race, marital status, insurance status, tumor site, tumor size, SEER stage, surgery, radiotherapy, and chemotherapy (Table 4). However, sex and grade did not significantly influence cumulative incidences of CVD. To minimize the risks of producing false positive results, multivariate analyses based on Fine-Gray hazard model were conducted to control the significant covariates. Results showed that age, race, marital status, tumor size, SEER stage, surgery, and chemotherapy were independent risk factors for CVD (Table 4).

### Construction of a Competing-Risk Model

The incidence of CVD in patients with CRC has tended to increase in the last decades. However, competing-risk model combining comprehensive factors for patients with CRC suffering CVD remains scarce. Thus, a nomogram predicting the probabilities of CVD at 1-, 3-, and 5-year was established (Figure 3) based on the Fine and Gray's model we built. With the help of this useful tool, an individual patient chance of CVD

at different times could be easily obtained by adding the scores of each incorporated variable.

### Validation and Risk Stratification of Competing-Risk Model

Then, this nomogram was validated using bootstrap and ten-fold cross-validation methods. The results showed that nomogram had a great discrimination ability in predicting overall survival (OS), with a C-index of 0.719 (95% CI, 0.738–0.742), and 0.719 (95% CI, 0.622–0.668) in the training and validation cohort, respectively. The calibration curves were shown in Figure 4, with the dots close to a 45° diagonal line, reflecting great consistency between the prediction by the nomogram and the actual observation of the probability of CVD at 1-, 3-, and 5-year. Furthermore, DCA was introduced to assess the clinical utility of the nomograms. As shown in Figures 5A,B, the clinical use of the nomogram showed high positive net benefits at a wider range

**FIGURE 4 |** The calibration curve for predicting the 1-, 3-, and 5-year probabilities of CVD in the training (A–C) and the validation cohort (D–F), respectively.

of threshold likelihood, which depicted that the nomogram had a high clinical utility in predicting CVD.

According to the tertile values of the nomogram-based scores derived from the training cohort, the patients were categorized into high-risk, medium-risk, and low-risk groups in both cohorts. The high-risk group had the highest probabilities of CVD, followed by the medium-risk group and the low-risk group in both cohorts (**Figures 5C,D**). Hence, there is an important value of competing-risk model for clinical risk stratification and prognosis decision in patients with CRC.

## DISCUSSION

In the past few decades, considerable advances in management of cancer have greatly prolonged the survival of patients suffering from CRC. On the other hand, we can also expect that non-cancer mortalities will become more prevalent, dominated by cardiovascular disease. Based on the SEER database, our current study provided important insights into the risk of CVD among patients with CRC diagnosed between 2007 and 2015. In total, 79,455 patients died throughout the follow-up, of whom 56,185 (70.71%) succumbed to CRC and 23,270 (29.29%) died due to non-CRC, among which CVD accounted for 9,702 (41.69%), being the major cause of non-cancer deaths. The 1-, 3-, and 5-year CIF of CVD were 12.20, 24.25, and 30.51%, respectively, while the 1-, 3-, and 5-year CIF of no-CVD were 1.93, 4.13, and 4.77%, respectively, indicating that CVD has become a main reason of death among CRC survivors during the follow-up period. Through competing risk analyses, we further identified that age, race, marital status, tumor size, SEER stage, surgery,

and chemotherapy were independent risk factors for CVD. These results should not be ignored when evaluating the individual risks of CVD and work as an indication for more precise treatment and risk factors management, such as monitoring of blood sugar and hypertension and health education.

Currently, chemotherapy and widely used drugs for CRC, which involves several agents, such as oxaliplatin, fluorouracil, leucovorin, and so on (25, 26), are effective. Chemotherapy usually induces cardiotoxicity and increases CVD risk (27). In addition, drugs for CRC usually lead to higher CVD risk than the general population, particularly in the first few years of treatment (28). However, our analysis indicated that the risks of CVD were significantly lower among patients with CRC who were treated with chemotherapy than those were not. This result seemed to be contrary to the observed cardiotoxic effect of chemotherapy. However, consistent with the previous studies in other tumors (29, 30), this contradiction arises from the limited life expectancy of patients who received chemotherapy and succumbed to CVD events. Since the detailed information for chemotherapy regimen were missing in the SEER database, further investigation is required to clarify the effect of chemotherapy on the risk of CVD among patients with CRC. In addition, we also demonstrated that patients without cancer-direct surgery had an increased CVD compared to patients who received surgery, which was in line with previous findings (13, 31).

In recent years, the role of socioeconomic factors in influencing humans, including cultural and social values, insurance status, education level or employments status, and so on, are increasingly becoming the focus of medical attention (32, 33). In this study, we investigated the effects of insurance and marital status on the risks of CVD. Results showed that

the insured patients had lower risk of CVD compared with those who were uninsured. For now, battling CRC has been regarded as a time-consuming, multidisciplinary, and expensive process. Uninsured patients usually suffer the brunt of shortage of medical services and supplies. Furthermore, we demonstrated that, among CRC survivors, marital status was a protection factor against CVD. Marital status is a potential marker of mental status, lifestyle, and social and family support, which have greatly affected the outcomes of patients with cardiovascular disease (34). Patients who are married display less distress and anxiety than their unmarried counterparts after a diagnosis of cancer (35–37), and this could contribute to increased family support, medication compliance, and survival advantages to a large extent. In addition, from the perspective of biological

factors, a married status benefited to promote cardiovascular, endocrine, immune status, and nutrition behavior (34, 38). Collectively, we strongly recommend the integration of non-biological factors when assessing the individual risks of CVD among CRC survivors.

To facilitate patient counseling and clinical decision making, a prospective risk of potential cardiotoxicity for individual is imperative. From the clinical perspective, we constructed a competing-risk model with variables to investigate the probabilities of CVD at 1-, 3-, and 5-year. To the best of our knowledge, this is the first study that established and validated a competing-risk model based on the Fine-Gray proportional subdistribution hazard analysis to estimate the individual probabilities of CVD-specific mortality for patients

with CRC. All the variables included in this nomogram were easily available in clinical practice. With its aid, clinicians can more expediently devise clinical managements and, more importantly, remain vigilant for this complication when treating patients with CRC with immunotherapy. Our nomograms showed excellent accuracy and discriminative performance, as validated by C-index and calibration curves. Furthermore, we should be aware that high discrimination calibration does not necessarily imply an excellent clinical utility. Hence, DCA was employed to determine the clinical utility of this nomogram by calculating the net benefits at each risk threshold probability (23, 24). Results showed that using the nomogram to predict the probabilities of CVD provided more benefits. Collectively, these data demonstrated that this model had strong practicability and high reliability in the processes of clinical practice.

The major advantages of this study were that it had a large enough sample size and that it used competing risk analysis to investigate the risk of CVD among patients with CRC. Generally speaking, the SEER database, accounting for about a third of the United States population, provides large enough sample data to explore risk factors and further develop a nomogram based on competing risk analysis. More to the point, results from analyses that use population-level databases tend to be more generalizable and representative than those from single-center reports (24). Actually, sufficient incorporated samples are needed to guarantee the accuracy of nomograms, as demonstrated our recent publications (5, 18, 24). Notably, no competing-risk model has been established to evaluate the risk of CVD among patients with CRC so far. We established the first competing-risk model for these patients and made possible the individualized prediction of prognosis. Furthermore, our nomogram showed excellent discrimination power and clinical usefulness in clinical practice. In addition, the parameters included in the nomogram could be easily obtained in clinical practice.

Undoubtedly, this study was subject to several limitations. First, it had a retrospective design, making potential hidden biases. In addition, there is no way to know some the relevant information, such as gene mutations (HER-2 and RAS/RAF), making it impossible to adjust for these characteristics between the two groups. Second, the SEER database did not provide an explanation about comorbidity since it was a significant factor when physicians deciding treatment strategies. This lacking would, to certain degree, weaken the objectivity of our conclusions. In addition, it remains a main limitation that we established a model without comorbidity status. Third, data on chemotherapy regimen were not available in the

SEER database, and some of which is closely associated with cardiotoxicity. Finally, although the competing-risk model had excellent performance in predicting the probabilities of CVD, it was validated by an internal patient cohort. Thus, additional external data is needed to verify the performance of the model further.

## CONCLUSION

The present study was the first to use a competing-risk model to investigate the cumulative incidence and risk factors of CVD among patients with CRC. More importantly, we have successfully developed a nomogram for predicting the probabilities of CVD for patients with CRC. The internal and external validation demonstrated the excellent discrimination, calibration, and clinical usefulness of this model. With the help of this well-established nomogram, clinicians would make more individualized treatments, tighter control of modifiable risk factors, and follow-up schedules.

## DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/supplementary material.

## ETHICS STATEMENT

Approval was waived by the Local Ethics Committee, as Surveillance, Epidemiology, and End Results (SEER) data is publicly available and de-identified.

## AUTHOR CONTRIBUTIONS

TL and SZ were responsible for the conception and design of the study, assisted with the statistical analysis, and wrote and revised the manuscript. YW, PZ, and LA contributed to the data analysis and revision on the English language and grammar, and corrected the parts of the discussion. TL made the primary contribution in the later stage in the writing and modification of the manuscript, and review of the finalized article. All authors contributed to the article and approved the submitted version.

Myxomas represent the most common benign primary cardiac tumor, they usually grow out of the interatrial septum into the left atrium with a pedunculated base. Intracardiac masses can be found incidentally on imaging studies, but symptomatology may arise secondary to the mass effect, embolization, and valvular function impairment. We present the case of a 75-year-old woman who arrived at the emergency department with atrial fibrillation and NSTEMI segment elevation myocardial infarction (NSTEMI) secondary to a highly vascularized neoplasm visible by coronary angiography and angiotomography. Scarce reports show high quality multi-imaging assessment of significantly vascularized myxomas with such atypical presentation. High-definition imaging studies played a fundamental role in the surgeon's management of a mass with a complex neovascularization.

**Keywords:** myxoma, tumor, neovascularization, echocardiography, computed tomography angiography

## INTRODUCTION

Primary cardiac tumors are a rare entity with benign etiology in approximately 90%. Myxomas represent the most frequent type with almost 80% and tend to be located in the left atrium (1, 2). The clinical presentation depends on the location and size of the tumor, and whether it is associated with valvular insufficiency, obstruction, or embolic events. Such signs and symptoms may differ among them, such as dyspnea, pulmonary edema, auscultatory findings, and in cases of right-sided masses, foot edema, hepatomegaly, and even ascites.

Case series have shown a relatively high rate of neovascularization in left atrial myxomas (LAM), with an increased use of non-invasive imaging modalities such as Coronary Computed Tomography Angiography (CCTA) in the preoperative evaluation and characterization of highly vascularized neoplasms (3–5). We present a case in which a multi-imagen assessment was performed in order to understand the tumor's enormous blood supply, which influenced the surgical decisions and resulted in the complete recovery of the patient.

## CASE DESCRIPTION

A 75-year-old female was admitted into the emergency department due to acute chest pain and dyspnea. There was no history of cardiovascular risk factors, prior heart disease, or trauma and the patient was otherwise in good health. On physical examination, jugular ingurgitation and bilateral rales in pulmonary fields were identified, heart sounds were arrhythmic and tachycardic (150 bpm) without murmurs. Other vital signs showed hypotension (80/60 mmHg) and tachypnea (26 rpm). Chest x-ray depicted cardiomegaly, left and right atrial enlargement and signs of pulmonary congestion. An initial electrocardiogram demonstrated atrial fibrillation (AF) and ST segment depression in the anterolateral wall (V1-V5), suggestive of a non-ST segment elevation myocardial infarction (NSTEMI) (Table 1). Baseline cardiac enzymes assessment surpassed the upper limit for CK 2919 U/L, CK-MB 57.5 U/L, and troponin I 0.058 ng/mL.

Risk stratification scales were calculated, obtaining 189 and 4 points in the GRACE and TIMI scores, respectively. Initial management included double antiplatelet therapy with aspirin and clopidogrel, and anticoagulation with enoxaparin. The atrial fibrillation reverted with the administration of Lanatoside C.

## DIAGNOSTIC ASSESSMENT

The patient was initially managed as a NSTEMI, and an urgent coronary angiography (CA) was performed in order to discard coronary artery occlusion. The study showed abnormal and significant neovascularization within the left atrium and a 90% obstruction at the origin of the marginal branch, which

suggested neovascularization of an atrial mass. (Figures 1A,B and Supplementary Video 1).

Transthoracic echocardiogram (TTE) showed a large echogenic oval mass in the left atrium attached to the interatrial septum by a short pedicle measuring  $5 \times 7 \times 6$  cm, as well as moderate to severe mitral regurgitation (MR) by color-Doppler. The biventricular systolic function was normal (LVEF-63% and TAPSE-21 mm). Two dimensional-Doppler-transesophageal echocardiography showed a giant vascularized heterogeneous mass. 3D-TTE accurately identified the mass protruding through the mitral valve into the left ventricle during end-diastole and the 2D-TTE color flow and continuous wave Doppler in four chamber view showed a diastolic mitral peak velocity of 2.08 m/s, maximum gradient of 17 mmHg and mean gradient of 10.33 mmHg (Figures 2A–C and Supplementary Video 2).

After the echocardiographic findings, the heart team agreed on performing a CCTA, which showed a non-infiltrative and very vascularized mass attached to the interatrial septum (Figures 3A,B). A 3D-CCTA reconstruction additionally showed the significant vascularity of the tumor, characterized the anatomy of the coronary arteries and the origin of the neovascularization (Figure 3C). Double arterial blood supply was observed, with anomalous vessels arising from the right coronary artery and the circumflex artery (Figure 3D and Supplementary Video 3).

The patient was scheduled for surgical resection, which consisted of median sternotomy, and bicaval bypass with cardioplegic cardiac arrest. Before the tumor resection, the surgical team ligated both feeding arteries. An oval mass presenting multiple hemorrhagic areas within was removed and the final measurement was  $7 \times 4 \times 5$  cm. Pathologic findings were consistent with a LAM (Figures 4A–C).

One month after surgery, a 2D-TTE demonstrated a diastolic mitral peak velocity of 0.67 m/s, maximum gradient of 1.79 mmHg, and mean gradient of 1.07 m/s and mild MR (Figure 4D). Atrial fibrillation and tumor recurrence were not detected in the following 18 months of follow-up.

## DISCUSSION

The clinical presentation of left atrial tumors depends on location and size, and whether it is associated with valvular insufficiency, obstruction, or embolic events. The initial assessment of atypical presentations may be challenging. Regarding the case, the mechanisms responsible for the origin of the EKG findings and manifestations could be due to two different situations. Fast AF and hypotension may have resulted in an oxygen supply demand imbalance (type 2 NSTEMI), thus the absence of findings in the CA that could explain the ST segment abnormalities and the complete recovery after surgical removal. Similarly, LAM should always be considered as an embolic source in healthy patients with systemic thromboembolism, including coronary artery embolization, which is extremely rare (0.06%) (6). Spontaneous recanalization prior to CA could also explain the reported findings.

TABLE 1 | Timeline.

### Day 0

- A 75-year-old female was admitted into the emergency department due to acute chest pain and dyspnea.
- Chest x-ray evidenced cardiomegaly, atrial enlargement and pulmonary congestion.
- Electrocardiogram. Atrial fibrillation, non-ST segment elevation myocardial infarction.
- Laboratory. CK, CK-MB, and troponin I with increased values.
- Urgent coronary angiography showed abnormal neovascularity inside the left atrium and coronary artery disease.

### Day 1

- Transthoracic and transesophageal echocardiogram evidenced an enormous and highly vascularized mass in the left atrium.

### Day 2

- Coronary computed tomography angiography revealed the complex network of blood vessels inside the mass, which arised from the right coronary and circumflex arteries.

### Day 4

- Artery ligation and tumor resection.

### Day 6

- Histological confirmation of cardiac myxoma.

### Month 1

- Follow-up Doppler echocardiography demonstrated adequate recovery, mild mitral regurgitation, and no tumor recurrence.
- Patient is asymptomatic.

**FIGURE 1 |** Coronary angiography. **(A)** Left coronary artery showing abnormal vascular structures (arrow) suggestive of arteriovenous fistula and a highly vascularized mass. Marginal branch demonstrates proximal 90% obstruction (**Supplementary Video 1**). **(B)** Right coronary artery shows no obstruction, abnormal vascular structures are also present (arrow).

**FIGURE 2 |** Echocardiogram. **(A)** 2D-TTE four-chamber view shows a large echogenic oval mass that occupies practically the entire left atrium, with regular borders, heterogeneous echogenicity, adhered to the interatrial septum by a short pedicle and moderate to severe mitral regurgitation in the color Doppler. **(B)** 2D-Transesophageal echocardiogram and color-Doppler evidenced significant vascularization inside the mass. **(C)** 3D-TTE shows the mass protruding through the mitral valve into the left ventricle during end-diastole (**Supplementary Video 2**). Ao, aorta; RA, right atrium; RV, right ventricle; TTE, transthoracic echocardiogram; TV, tricuspid valve.

**FIGURE 3 | (A,B)** Coronary Computed Tomography Angiography. Hypodense mass located in the left atrium attached to the interatrial septum, with a dense network of blood vessels within. The intra-atrial mass protrudes through the mitral valve into the left ventricle during diastole, causing impairment of the atrial emptying and mitral valve closure. **(C,D)** Coronary Computed Tomography Angiography reconstruction. Complex blood vessel network (arrows) anastomosed to branches of the circumflex artery and the right coronary artery (**Supplementary Video 3**). Ao, aorta; Cx, circumflex artery; LA, left atrium; LV, left ventricle; RCA, right coronary artery.

In any case, the cardiac territory supplied by an obstructed artery is at increased risk of hypoxic cell injury, as seen during CA in the marginal branch, which showed a concomitant luminal reduction of 90%, which may have further contributed to the initial presentation in our patient.

Imaging evaluation of a cardiac mass includes echocardiography as the initial study to determine its location, size, and mobility. Other imaging modalities are required to visualize the characteristics of the coronary arteries and their relationship to the neovascularization that can be found in myxomas, however, these techniques may not be routinely available in some countries and were highly underused a few years ago, as described by Elbardissi et al. (7), when they evaluated 278 patients with cardiac masses, which were mainly diagnosed by echocardiography and only a few underwent CA ( $n = 33$ , 10%) or CCTA ( $n = 9$ , 3%). Case series have shown a relatively high rate of low neovascularization in myxomas, with an increased and standardized use of new imaging modalities

such as cardiac magnetic resonance imaging (MRI) and CCTA for evaluating this type of tumors, either as a complementary tool of CA or by replacing it (3–5). CCTA overcomes the limitations of echocardiography and CA by displaying detailed images of the origin and morphology of tortuous and dilated blood vessels; and, at the same time, reliably ruling out coronary artery disease (CAD) in patients scheduled for surgical resection (4).

Kim et al. (5) described 2 patients who were initially diagnosed with LAM by echocardiography and subsequently underwent preoperative CCTA instead of coronary angiography to rule out concomitant CAD, which provided more information about the vasculature of the mass. On the other hand, this technique avoids the risk of embolization and other complications of CA and can provide information that modifies the chosen surgical method, such as ligation of the feeding arteries before surgical resection (4).

Differential diagnosis of LAM mainly includes cardiac malignant tumors such as angiosarcoma and thrombi. Large

**FIGURE 4 |** Macroscopic and microscopic specimen findings. **(A)** Oval mass of 80 grams, 7 × 4 × 5 cm of diameter with a smooth surface showing white/yellow colors with zones of hemorrhagic aspect. Intact capsule that delimits the entire mass, compatible with its benign and non-invasive nature. **(B)** On the left side, a pattern of glanduloid/vascular cavities with abundant inflammatory lymphocytic infiltrate. On the right side, homogeneous stroma with clear spaces and isolated myxoma cells with fusi morphology. H/E10x **(C)** Myxoma's stroma shows decreased cellular density and multiple blood vessels (asterisks). Stellate appearance cells present eosinophilic cytoplasm and round nucleus (white arrow). Syncytial Cells with a string morphology (black arrow). H/E 40x. **(D)** Follow-up echocardiogram. 2D and color flow TTE in four-chamber view with 2 jets of mild mitral regurgitation (white arrows) and no cardiac mass in the left atrium. Abbreviations as before.

thrombi may represent a diagnostic challenge by using echocardiography alone, but characteristic findings include attachment to the posterior left atrial wall, a broad base and tend to be immobile, contrary to LAM. Additionally, malignant tumors tend to be highly vascularized masses which can be observed by using contrast echocardiography, which provides specific information for differentiating malignant from benign neoplasms. If low vascularization is present, slow contrast filling of the mass would be observed, as usually occurs in benign tumors, such as cardiac myxomas. In this particular case, due to the extreme vascularization, a contrast agent would show a rapid filling and late opacification, simulating a malignant process, which emphasizes the importance of pathologic findings for the final diagnosis of a cardiac tumor. Regarding thrombi, which are usually not vascularized, contrast echocardiography would show no filling of the contrast agent (8).

As mentioned, the pathological findings represent a fundamental tool for the final diagnosis of a cardiac mass, whereas a multi-imaging evaluation helps in the assessment of the morphology and characteristics of the tumor and its relationship with the surrounding cardiac and paracardiac structures, and therefore is particularly useful for the surgeon in order to precisely plan the surgical intervention.

In our case, CCTA showed that the tumor's enormous blood supply came from the right coronary and circumflex arteries, which helped the heart team understand the complexity of

the myxoma vasculature and ligate both feeding arteries before the mass resection. Therefore, CCTA may confer a better alternative than CA in the evaluation of cardiac masses and in their differential diagnosis, especially in the context of a highly vascularized myxoma and when the patient is older than 40 years to rule out concomitant CAD.

On the other hand, cardiac MRI provides images suitable for the same purpose without exposing the patient to ionizing radiation, but it relies on patient cooperation, implanted magnetic devices, and is less useful than CCTA in evaluating coronary arteries during an acute event, which may be very important in the context of LAM, specifically in urgent atypical presentations as the one described in this case.

For the preoperative evaluation of myxomas, an imaging modality such as MRI, CCTA or CA must be performed in order to better characterize the mass and evaluate CAD. Preoperative CCTA represents an accurate method to assess myxoma morphology, vascularization, and avoids CA risks. Three-dimensional reconstructions may be even more useful in the decision making of the surgical team.

## ETHICS STATEMENT

The studies involving human participants were reviewed and approved by the Research and Ethics Committee of National Institute of Cardiology Ignacio Chavez. The patients/participants provided their written informed consent to participate in this study. The patients/participants provided their written informed consent for the publication of the case report, and for the publication of any potentially identifiable images or data included in this article.

## AUTHOR CONTRIBUTIONS

JS-R, SS-A, and NE-Z collected the data and headed the elaboration of the present manuscript. VF-B, ES-P, and AE-G reviewed the recent literature. JA-F performed the echocardiogram and analyzed the CCTA. JB and MG-C carefully revised the manuscript. AA-F interpreted the macroscopic and

microscopic images. All authors contributed to the conception, analysis, and design of the complete case report, revising of the manuscript, enhancing its intellectual content, and approving the final version of the manuscript.

## FUNDING

This work was supported by the National Institute of Cardiology Ignacio Chávez.

## ACKNOWLEDGMENTS

We acknowledge the heart team of the National Institute of Cardiology Ignacio Chávez.

# Primary site as a novel prognostic factor for cardiovascular mortality post-radiotherapy in limited-stage small cell lung cancer: A large population-based study

Yuwei Zhao<sup>1</sup>, Fen Qin<sup>2</sup>, Qingqi Ji<sup>1</sup>, Wuyan Xia<sup>3</sup> and Ben He<sup>1,4\*</sup>

<sup>1</sup>Department of Cardiology, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China, <sup>2</sup>Department of Cardiology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, <sup>3</sup>Department of Radiation Oncology, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China, <sup>4</sup>Clinical Research Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China

**Background:** The effect of primary site on cardiovascular mortality (CVM) post-radiotherapy (RT) in patients with limited-stage small cell lung cancer (LS-SCLC) remains unclear.

**Methods:** We screened the Surveillance, Epidemiology, and End Results (SEER) database between 1988 and 2013. We used cumulative incidence function (CIF) curves to compare CVM incidences, and performed Cox proportional hazards and Fine-Gray competing risk analyses to identify independent risk factors of CVM. Propensity score matching (PSM) analysis was conducted.

**Results:** Among enrolled 4,824 patients (median age 57 years old, 49.2% were male), CVM accounts for 10.0% of all deaths after 5 years since cancer diagnosis. Hazard ratios (HRs) for CVM were 1.97 (95% CI: 1.23–3.16,  $P = 0.005$ ) for main bronchus (MB) patients, 1.65 (95% CI: 1.04–2.63,  $P = 0.034$ ) for lower lobe (LL) patients and 1.01 (95% CI: 0.40–2.59,  $P = 0.977$ ) for middle lobe (ML) patients compared to upper lobe (UL) patients. CIF curves showed that the cumulative CVM incidence was greater in the re-categorized MB/LL group compared to UL/ML group both before PSM ( $P = 0.005$ ) and after PSM ( $P = 0.012$ ). Multivariate regression models indicated that MB/LL was independently associated with an increased CVM risk, before PSM ( $HR_{Cox}$ : 1.79, 95% CI: 1.23–2.61,  $P = 0.002$ ;  $HR_{Fine-Gray}$ : 1.71, 95% CI: 1.18–2.48,  $P = 0.005$ ) and after PSM ( $HR_{Cox}$ : 1.88, 95% CI: 1.20–2.95,  $P = 0.006$ ;  $HR_{Fine-Gray}$ : 1.79, 95% CI: 1.15–2.79,  $P = 0.010$ ).

**Conclusions:** MB/LL as the primary site is independently associated with an increased CVM risk post-RT in patients with LS-SCLC.

## KEYWORDS

small cell lung cancer, radiotherapy, tumor primary site, cardiovascular mortality, SEER

## Introduction

Radiotherapy (RT) is frequently used as an essential adjuvant to chemotherapy or surgery in thoracic malignancies. RT has been shown to improve cancer-specific survival; however, it has been implicated in pulmonary and cardiac complications because of reported acute and chronic radiation-induced injuries to healthy tissues in the radiation field (1–4). Some reports have focused on cardiovascular toxicities post-thoracic RT in long-term cancer survivors, including those with breast cancer and Hodgkin lymphoma (3, 5–7).

Lung cancer is a major malignancy that accounts for the highest morbidity and mortality rates worldwide (8). Adverse effects of RT on the cardiovascular system in patients with lung cancer have recently attracted wider attention and have gained increasing interest in the field of cardio-oncology. Previous studies have shown that RT could increase the incidence of cardiovascular complications in patients with non-small cell lung cancer (NSCLC) (9–14). However, investigations on RT-related cardiovascular sequelae in patients with limited-stage small cell lung cancer (LS-SCLC) remain scarce. This may be partially because, historically, LS-SCLC was considered to have an unfavorable median overall survival (OS) of approximately 1 year before the 1990s (15). Nevertheless, survival rates for patients with LS-SCLC have gradually improved due to widespread application of early chest CT screening in high-risk populations, advanced modern RT techniques, more accurate staging paradigms, and recent promising treatment strategies (16, 17). Thoracic RT combined with chemotherapy (CTX) is considered the first-line standard therapy for LS-SCLC (16, 17). However, more extensive studies are needed to evaluate RT-related cardiovascular toxicities in patients with LS-SCLC.

The primary site as a conventional clinical characteristic affecting a lung cancer treatment strategy has currently been recognized as an important prognostic factor for OS and tumor-specific prognosis (18–20). With a disparity in the distance between tumor location and heart/great vessels, potential RT-induced cardiovascular injury may be further distinctive risk (21); however, few relevant reports are available.

This study aimed to identify significant prognostic factors concerning CVM post-RT for patients with LS-SCLC, and to explore the effect of different primary site-based RTs on CVM in a large population of patients with LS-SCLC using data from the Surveillance, Epidemiology, and End Results (SEER) database.

## Materials and methods

### Patients and data sources

The SEER database [SEER 18 Regs Custom Data (with additional treatment fields), November 2018 Sub] was queried using SEER\*Stat software (version 8.3.6). Inclusion criteria

for patients were as follows: patients aged  $\geq 18$  and  $< 65$  years and diagnosed with LS-SCLC between 1988 and 2013; patients treated with external beam RT, and; patients with only one primary tumor, a positive histology, available clinical information, active follow-up, and complete dates. Older adult patients with more confounding factors such as coronary heart disease (CHD), hyperlipidemia, hypertension, and diabetes mellitus (DM) were not enrolled for the purpose of alleviating, at least partially, the effects of confounders on CVM in patients post-RT (1, 2, 14), and because younger patients are reported to be more vulnerable to radiation-induced cardiovascular injury (22). The specific time period of 1988–2013 was selected because American Joint Committee on Cancer (AJCC) staging for SCLC in the SEER database started in 1988, whereas 2013 was the final year for analysis in which adequate follow-up to assess post-treatment CVM was possible. Exclusion criteria included: unknown race, not the only primary cancer, receipt of surgical treatment, no/unknown external beam radiation, no/unknown chemotherapy, bilateral or unknown laterality, overlapping or unknown primary site or loss of follow-up information. Inclusion and exclusion criteria for the study population is outlined in Figure 1.

AJCC, American Joint Committee on Cancer; CVM, cardiovascular mortality; NCVM, non-cardiovascular mortality. Percentages might not add up to 100% because of rounding.

This study was conducted in accordance with the Declaration of Helsinki (as revised in 2013) and complied with the requirements of the Institutional Review Board of Shanghai Chest Hospital, Shanghai Jiao Tong University. The authors have gotten the access to and approval from the SEER database (accession and approval number: 13236–November 2019). The need for informed consent has been waived due to the retrospective nature of the study and because SEER database is a public anonymized database.

## Definition of LS-SCLC

LS-SCLC was defined as AJCC stage I–III malignancies with primary sites in the lung or bronchus [International Classification of Diseases for Oncology-3 (ICD-O-3)/WHO 2008: Lung and Bronchus]. Histological types were as follows: ICD-O-3 codes: 8002, 8041–8045. Primary sites were as follows: main bronchus (MB) (C34.0), upper lobe (UL) (C34.1), middle lobe (ML) (C34.2), and lower lobe (LL) (C34.3).

## Research variables

Demographics and clinicopathologic data, such as age, sex, race, marriage, year of diagnosis, AJCC stage, laterality and primary site were collected. CVM was defined as death due to cardiovascular diseases using the following ICD-10 codes: I00–I52 and I70–I79, including conditions such as diseases of the heart, hypertension without heart disease, atherosclerosis, aortic aneurysm and dissection, and other diseases of the arteries, arterioles, and capillaries. Non-cardiovascular mortality (NCVM) was defined as death due to other causes, excluding CVM.

## Statistical analysis

Statistical analysis was performed using either R (version 3.6.0, R Foundation for Statistical Computing, Vienna, Austria) or Stata (version 15.0, College Station, Texas, USA) software. All statistical tests were two-sided, and the significance level was set at 0.05. As the only continuous variable, age was expressed as median [with inter-quartile range (IQR)] for non-normally distributed data and compared using a Kruskal–Wallis test between the groups. Categorical variables were expressed as numbers (percentages) and then compared using a chi-square test.

We generated cumulative incidence function (CIF) curves using univariate Fine-Gray competing risk regression models to compare the cumulative incidences of CVM or NCVM between the groups. Univariate and multivariate Cox proportional hazards regression models were applied to identify factors associated with CVM or NCVM risk. Based on results obtained from multivariate Cox proportional hazards regression models, the UL and the ML as primary sites were re-categorized into a UL/ML group, and the MB and the LL were combined to form a MB/LL group. Accounting for mortality from other causes, univariate and multivariate Fine-Gray competing risk regression models (23) were used to validate factors associated with CVM risk and obtain more accurate results. The propensity score matching (PSM) method (24, 25) was used to balance the baseline bias between the UL/ML and MB/LL groups. A greedy

FIGURE 2

CVM post-radiotherapy as a proportion of all deaths within a given time period after LS-SCLC diagnosis. CVM, cardiovascular mortality; LS-SCLC, limited-stage small cell lung cancer.

matching algorithm was used for PSM and the caliper was set at 0.02.

## Results

### Patient demographics and clinical characteristics

A flowchart indicating inclusion and exclusion for the study population is outlined in [Figure 1](#). We enrolled 4,824 patients with LS-SCLC {median age, 57 [interquartile range (IQR), 52–61] years; males, 49.2%}, of whom 2,487 (51.6%) were ≤57 years old, 2,373 (49.2%) were male, and 84.4% were of White ethnicity. There were 1,957 (40.6%) and 2,717 (56.3%) unmarried and married patients, respectively. In addition, 2,118 (43.9%) patients had been diagnosed with LS-SCLC in the 1988–2003 period, and 2,706 (56.1%) patients in the 2004–2013 period. In terms of AJCC stage, 15.0% and 85.0% of patients were classified in Stage I-II and Stage III, respectively. In terms of laterality, 1,965 (40.7%) patients had left-sided tumors and 2,859 (59.3%) had right-sided tumors. In terms of primary site tumor location, 2,890 (59.9%) patients had primary site tumors in the

UL, 247 (5.1%) patients had primary site tumors in the ML, 748 (15.5%) patients had primary site tumors in the MB, and 939 (19.5%) patients had primary site tumors in the LL.

The overall incidence of CVM and NCMV at the follow-up endpoint (November 2018) was 2.3 and 87.3%, respectively. Baseline clinical and prognostic characteristics concerning the study population are shown in [Table 1](#). The percentage of deaths due to cardiovascular diseases following diagnosis was tabulated ([Figure 2](#)). Within the first year of diagnosis, 1.9% of all deaths were CVM-related and this percentage increased from 1.7% in year two to 2.7% in year three, to 3.4% in year four, to 7.7% in year five, and to 10.0% after 5 years, showing an increasing trend for percentage of deaths due to CVM along with patients' survival time.

### Analysis of CVM based on different variables

Primary sites were initially divided into UL, ML, MB, and LL groups. CIF curves showed no significant differences in cumulative incidences of CVM between groups according to age,

**FIGURE 3**  
 CIF curves of CVM by different variables in LS-SCLC patients. **(A)** Age; **(B)** Sex; **(C)** Race; **(D)** Marriage; **(E)** Year of diagnosis; **(F)** AJCC stage; **(G)** Laterality; **(H)** Primary site (stratified into UL, ML, MB and LL groups). CVM, cardiovascular mortality; HR, hazard ratio; CI, confidence interval; AJCC, American Joint Committee on Cancer.

sex, ethnicity, marital status, AJCC stage, or laterality (all  $P > 0.05$ , **Figures 3A–D,E,G**). A comparison between time periods for diagnosis showed a significantly higher cumulative incidence of CVM in the 1988–2003 period relative to the 2004–2013 period ( $P = 0.012$ , **Figure 3E**). Additionally, there was a significant difference between the four groups in terms of the primary sites ( $P = 0.034$ , **Figure 3H**).

Multivariate Cox proportional hazards regression models showed independent predictors of CVM risk in patients with LS-SCLC, including sex [female vs. male: hazard ratio (HR) 0.59, 95% confidence interval (CI) 0.40–0.87;  $P = 0.007$ ], time period for diagnosis (2004–2013 vs. 1988–2003, HR 0.64, 95% CI 0.43–0.95;  $P = 0.028$ ), and primary site (ML vs. UL, HR 1.01, 95% CI 0.40–2.59,  $P = 0.977$ ; MB vs. UL, HR 1.97, 95% CI 1.23–3.16,  $P = 0.005$ , and; LL vs. UL, HR 1.65, 95% CI 1.04–2.63,  $P = 0.034$ ). A summary of the results of Cox proportional hazards regression models used to predict CVM risk are listed in **Table 2**.

## Analysis of CVM based on primary site stratification across UL/ML and MB/LL groups before and after PSM

Based on the results obtained from multivariate Cox proportional hazards regression models, patients with UL and

ML primary site tumors were grouped together into a UL/ML group, and patients with MB and LL primary site tumors were combined to form an MB/LL group. The proportion of patients with left-sided primary site tumors was significantly higher in the MB/LL group than in the UL/ML group before PSM (45.1 vs. 38.4%,  $P < 0.001$ ). To prevent baseline bias, 1,687 patients in the UL/ML group were matched 1:1 with those from the MB/LL group using the PSM method, which showed a good match in terms of demographic and clinicopathologic characteristics (**Table 3**). We found a higher CVM incidence at the end of the follow-up (November 2018) in patients in the MB/LL group compared to those in the UL/ML group. We observed a before PSM CVM incidence of 3.2% and 1.9% ( $P = 0.005$ ) in the MB/LL and UL/ML groups, respectively, and 3.2 and 1.8% ( $P = 0.011$ ) after PSM, respectively (**Table 3**). CIF curves showed that the cumulative CVM incidence was significantly higher in the MB/LL group than in the UL/ML group before PSM ( $P = 0.005$ , **Figure 4A**) and after PSM ( $P = 0.012$ , **Figure 4B**).

Regression analyses showed that MB/LL primary site tumors were independently associated with an increased CVM risk compared with UL/ML primary site tumors in patients with LS-SCLC before and after PSM (**Tables 4, 5**). Specifically, multivariate Cox models showed an HR of 1.79 (95% CI 1.23–2.61,  $P = 0.002$ ), whereas multivariate Fine-Gray models indicated an HR of 1.71 (95% CI 1.18–2.48,  $P = 0.005$ ) before

LS-SCLC, limited-stage small cell lung cancer; UL/ML, upper lobe/middle lobe; MB/LL, main bronchus/lower lobe; PSM, propensity score matching; AJCC, American Joint Committee on Cancer; CVM, cardiovascular mortality; NCVM, non-cardiovascular mortality. Percentages might not add up to 100% because of rounding.

PSM in patients with LS-SCLC in the MB/LL group compared with those in the UL/ML group (Table 4). After PSM, an HR of 1.88 (95% CI 1.20–2.95,  $P = 0.006$ ) and an HR of 1.79 (95% CI 1.15–2.79,  $P = 0.010$ ) were recorded for multivariate Cox proportional hazards regression and Fine-Gray models, respectively, for patients with LS-SCLC in the MB/LL group compared with those in the UL/ML group (Table 4).

CIF curves showed that cumulative CVM incidences were both significantly lower in the 1988–2003 period relative to the 2004–2013 period for diagnosis before PSM ( $P = 0.012$ , Figure 4C) and after PSM ( $P = 0.004$ , Figure 4D). Regression analyses, based on Cox proportional hazard regression and Fine-Gray competing risk models, showed that the 2004–2013 period was independently associated with lower CVM risk

relative to the 1988–2003 before and after PSM (all  $P > 0.05$ , Tables 4, 5).

## Analysis of NCVM based on different variables

There were no significant differences in cumulative NCVM incidences between the UL/ML and the LL/MB groups before PSM ( $P = 0.442$ , Figure 5A) and after PSM ( $P = 0.324$ , Figure 5B). The univariate and multivariate Fine-Gray competing risk regression analyses showed that primary site was not an independent predictor of NCVM post-RT in patients with LS-SCLC ( $P > 0.05$ , Supplementary Tables 1, 2).

**FIGURE 4**  
CIF curves of CVM stratified into UL/ML and MB/LL groups by primary site before (A) and after (B) PSM and stratified into 1988–2003 and 2004–2013 groups by year of diagnosis before (C) and after (D) PSM in LS-SCLC patients. CIF, cumulative incidence function; CVM, cardiovascular mortality; UL/ML, upper lobe/middle lobe; MB/LL, main bronchus/lower lobe; PSM, propensity score matching; LS-SCLC, limited-stage small cell lung cancer.

## Discussion

### Prior works

Studies have shown that RT can increase incidence of cardiovascular complications in lung cancer patients (9–14, 26, 27). For instance, Lally et al. (9) implicated postoperative RT with increased cardiac mortality in NSCLC patients. In the Radiation Therapy Oncology Group (RTOG) 0617 NSCLC trial, heart V5 (volume of heart receiving 5 Gy) and heart V30 were associated with increased risk of cardiac events (CE) as well as inferior survival rates (10). Dess et al. (11) presented a long-term grade 3 CE incidence, exceeding 10%, among a prospective locally advanced NSCLC (LA-NSCLC) cohort. In an analysis of prospective dose-escalation LA-NSCLC trial, Wang et al. (12) demonstrated that the radiation dose delivered to the heart was an independent predictor of CE. In addition, results of a SEER database analysis (13) among 52,624 LA-NSCLC patients receiving thoracic RT, showed that cardiac-specific mortality

(CSM) in left-sided patients was significantly higher than that in right-sided patients. A recent study suggested that mean heart dose was a risk factor for major adverse cardiac events and all-cause mortality in a single-institution retrospective cohort study of LA-NSCLC patients (14).

In recent years, research focus has been directed toward long-term RT-related cardiovascular sequelae in patients with SCLC, due to parallels with NSCLC and the rise in life expectancy (16, 17). Ferris et al. (26) performed a data analysis using the SEER database and found that RT was associated with an approximate 10% absolute increase in CE at 5 years in patients with LS-SCLC and multivariate analysis has shown an independent association between RT and CE. A recent SEER database study showed an increased CSM in left vs. right-sided patients with LS-SCLC receiving thoracic RT (27). Currently, no prior study has investigated the effect of primary site on cardiovascular complications especially concerning CVM in patients with LS-SCLC post-RT. Our study has contributed an enhanced understanding to this research field.

# Main findings

This study was the first to report the effects of primary site on CVM post-RT in patients with LS-SCLC. Our results showed that patients in the MB/LL group had a significantly higher cumulative CVM incidence than those in the UL/ML group. MB/LL as the primary site was associated with an increased risk of CVM, and the primary site was a novel prognostic factor for CVM post-RT. This study has many highlights and high reliability of the results. First, we used PSM to balance demographic and clinicopathologic characteristics. These characteristics, especially laterality, have been previously shown to affect occurrence of cardiovascular events in patients with cancer treated with thoracic RT (9, 13, 27). Previous SEER-based analyses involving patients with LA-NSCLC (13) or patients with LS-SCLC (27) receiving thoracic RT showed that CSM in patients with left-sided tumors was significantly higher than that in patients with right-sided tumors. In our study, the percentage of patients with left-sided tumors was significantly greater in the MB/LL patient group than in the UL/ML patient group; therefore, PSM was performed to eliminate possible laterality bias on CVM. Second, rather than using the Kaplan-Meier method, Fine-Gray competing risk regression models (23) that can correctly estimate the probability of an event

in the presence of competing events were used in survival analysis to validate the results of Cox proportional hazards regression models. Third, we restricted our analysis to patients aged <65 years. Bias may be present and affect CVM results when comparing patients among all age groups in terms of an unbalanced burden of cardiovascular comorbidities. To address this challenge, we only enrolled patients aged <65 years to help determine any correlation between thoracic RT and CVM risk. We envisaged that this would minimize the effect of underlying cardiovascular risk factors or comorbidities on CVM occurrence. After taking these matters into account, we consider that this study provides a more accurate and reliable evaluation of the effect of thoracic RT on CVM in patients with SCLC.

# Risk factors affecting CVM and potential mechanisms

Thoracic RT has been shown to result in injury to the heart and coronary artery, as well as to other vessels in the radiation field, including the aorta and pulmonary artery, resulting in aortic valve disease, porcelain aorta, and pulmonary artery aneurysm (28–31). The relative anatomical position between a tumor primary site and heart/great vessels might influence

CVM, cardiovascular mortality; PSM, propensity score matching; HR, hazard ratio; CI, confidence interval; AJCC, American Joint Committee on Cancer; UL/ML, upper lobe/middle lobe; MB/LL, main bronchus/lower lobe.

the amount of radiation doses received by the heart or great vessels during RT. Anatomically, the LL is closely adjacent to the heart, and has been found to be associated with larger volume variability than the UL during radiation procedures (21). Furthermore, bilateral main bronchi are embedded in the hilum of the lung and are surrounded with several great

vessels. Specifically, the right MB passes behind the ascending aorta, the superior vena cava, and the right pulmonary vessels, whereas the left MB passes behind the left pulmonary vessels, and extends across the arch formed by the arch of the aorta and the descending thoracic aorta. This close anatomical relationship makes it more likely for healthy tissues to receive additional

radiation exposure, especially heart and great vessel tissues located adjacent to the tumor in patients whose primary site is located in the MB and in the LL, consequently making them more vulnerable to radiation-induced injury. Recent clinical studies have reported that patients with NSCLC with primary sites in the left MB and left LL have lower OS rates (18–21). To date, the specific mechanism to explain this remains unclear, although it may be attributed, at least in part, to increased RT-induced severe adverse cardiovascular events in patients receiving RT with primary sites in the MB and LL (9–14). This explanation accords with our study findings. Two studies have shown that in patients with cancer receiving thoracic RT, left-sided laterality was associated with an increased incidence of cardiovascular complications, due to a shorter distance between the left-sided radiation field and the heart compared with patients with right-sided primary sites (13, 27). This finding provides support for the potential mechanisms involved concerning distinct incidences of CVM in different primary sites in our study.

## Limitations

Although this study provides novel and clinically significant insights into CVM post-RT for patients with non-surgical LS-SCLC, there remain some limitations inherent to any retrospective analysis. First, the SEER database contains limited data concerning pre-existing cardiovascular comorbidities and risk factors. Next, similar to previous RT studies based on data from the SEER database (13, 26), we were unable to assess many important therapeutic parameters, such as total radiation dose, the dose per fraction, the volume of heart/great vessels irradiated, and chemotherapy agents. The validity of reporting RT using SEER data has been questioned. However, one recent study reported a high sensitivity and positive predictive value between RT records and the actual implementation of RT (32). Additionally, given the *post-hoc* nature of this study, limitations in terms of retrospective analyses apply. Nonetheless, MB/LL and UL/ML groups were matched to obviate the potential effect of unbalanced variables on CVM.

## Conclusions

MB/LL as the primary site was found to be associated with an increased risk of CVM post-RT in patients with LS-SCLC. This study presented a propensity score-matched competing risk analysis in a large, population-based, real-world cohort, with which to analyze RT-linked sequelae and to stratify CVM risk during clinical decision-making. Our findings suggested that patients with MB/LL tumors undergoing RT may require better radioprotection not only for the heart, but also for the great vessels. More comprehensive cardiovascular management

and closer follow-up are needed for patients with LS-SCLC undergoing RT.

## Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## Ethics statement

Ethical review and approval was not required for the study on human participants in accordance with the local legislation and institutional requirements. Written informed consent for participation was not required for this study in accordance with the national legislation and the institutional requirements.

## Author contributions

YZ contributed to writing the manuscript, SEER database access, and data acquisition and analysis. YZ, FQ, and BH contributed to the conception, design, and supervision of the study. QJ and WX contributed to data interpretation. All authors contributed to the article and approved the submitted version.

## Funding

This work was supported by the National Natural Science Foundation of China (81830010), the Artificial intelligence project of Xuhui District, Shanghai (No. 2020-011), Clinical Research Plan of SHDC (SHDC2020CR1039B), Shanghai Jiao Tong University School of Medicine clinical research project (dly201512).

## Acknowledgments

The authors would like to thank the Surveillance, Epidemiology, and End Results (SEER) Program tumor registries in the creation of the SEER database.

## Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

**Background:** Immune checkpoint inhibitors (ICIs) have significantly changed the oncology clinic in recent years, improving survival expectations in cancer patients. ICI therapy have a broad spectrum of side effects from endocrinopathies to cardiovascular diseases. In this study, pro-inflammatory and pro-fibrotic effects of short-term ICIs therapy in preclinical models were analyzed.

**Methods:** Firstly, in a human *in vitro* model, human cardiomyocytes co-cultured with hPBMC were exposed to ICIs (with CTLA-4 or PD-1 blocking agents, at 200 nM) for 72 h. After treatment, production of DAMPs and 12 cytokines were analyzed in the supernatant through colorimetric and enzymatic assays. C57/BL6 mice were treated with CTLA-4 or PD-1 blocking agents (15 mg/kg) for 10 days. Before (T0), after three days (T3) and after treatments (T10), ejection fraction, fractional shortening, radial and longitudinal strain were calculated by using bidimensional echocardiography (Vevo 2100, Fujifilm). Fibrosis, necrosis, hypertrophy and vascular NF- $\kappa$ B expression were analyzed through Immunohistochemistry. Myocardial expression of DAMPs (S100- Calgranulin, Fibronectin and Galectine-3), MyD88, NLRP3 and twelve cytokines have been analyzed. Systemic levels of SDF-1, IL-1 $\beta$ , and IL-6 were analyzed before, during and after ICIs therapy.

**Results:** Radial and longitudinal strain were decreased after 10 days of ICIs therapy. Histological analysis of NF- $\kappa$ B expression shows that short-term anti-CTLA-4 or anti-PD-1 treatment increased vascular and myocardial inflammation. No myocardial hypertrophy was seen with the exception of the pembrolizumab group. Myocardial fibrosis and expression of galectin-3, pro-collagen 1- $\alpha$  and MMP-9 were increased after treatment with all ICIs. Both anti-CTLA-4 or anti-PD-1 treatments increased the expression of DAMPs, NLRP3 inflammasome and MyD88 and induced both *in vitro* and *in vivo* the secretion of IL-1 $\beta$ , TNF- $\alpha$  and IL-6. Systemic levels of SDF-1, IL-1 $\beta$  and IL-6 were increased during and after treatment with ICIs.

**Conclusions:** Short therapy with PD-1 and CTLA-4 blocking agents increases vascular expression of NF- $\kappa$ B, systemic SDF-1, IL-1 $\beta$ , IL-6 levels and myocardial NLRP3, MyD88 and DAMPs expression in preclinical models. A pro-inflammatory cytokine storm was induced in myocardial tissues and in cultured cardiac cells after ICIs therapy. The overall picture of the study suggests new putative biomarkers of ICIs-mediated systemic and myocardial damages potentially useful in clinical cardioncology.

## Introduction

Immune checkpoint inhibitors (ICIs) includes monoclonal antibodies that activate the host immune system for efficient killing of cancer cells through unspecific activation mechanisms (1). ICIs are directed against programmed cell death protein (PD-1), its associated ligand (PD-L1) or CTLA-4 (Cytotoxic T-Lymphocyte Antigen 4) leading to activation of lymphocytes and NK cell activity against cancer cells (2, 3). Clinical benefits were seen in melanoma, non-small cell lung cancer and metastatic breast cancer patients; association therapies with radiotherapy or chemotherapy or with other ICIs are still proposed worldwide (2). ICIs-mediated side effects involves T-lymphocyte-driven inflammation and direct cytotoxicity in many tissues, such as skin, intestine, lungs, liver, endocrine organs and cardiovascular system (4, 5). ICIs mediated cardiotoxicities are rare but can affect anticancer regimens and quality of life in cancer patients (6). Cardiovascular complications in cancer patients treated with ICIs include fatal myocarditis, vasculitis, arrhythmia, fibrosis and heart failure (7, 8). In different types of cancer, different ICIs may show different cardiotoxicity spectra (9). The incidence of ICIs-related cardiovascular events ranged from 0.15 to 10%. For example, in melanomas, PD-1/PD-L1 inhibitor use was closely related to high blood pressure and myocarditis (8, 9). Lung cancer patients, commonly experienced acute coronary syndrome, arrhythmia and heart failure (9). The most common cardiotoxic events after nivolumab and pembrolizumab therapy in lung cancer patients are arrhythmia,

cardiac-related chest pain, cardiomyopathy, and myopericardial diseases. Moreover, renal cell carcinomas patients treated with nivolumab associated to ipilimumab frequently experienced hypertension (9); patients with urothelial carcinoma treated with atezolizumab had frequently hypertension and arrhythmia. Therefore, a complex interaction between cancer-related and immune-related factors plays a key role in pathogenesis of cardiovascular toxicities.

Known mechanisms of ICIs-induced cardiotoxicity involves immune-infiltration of CD3 +, CD4 + and CD8 + T lymphocytes in myocardial tissues that can attack cardiomyocytes or endothelial cells leading to metabolic failure and reduced cell viability (10, 11). Notably, ICIs can induce a pro-inflammatory phenotype in cardiac and vascular tissues therefore the identification of new players of cardiotoxicity mediated by short-term ICIs therapy still need further attention. Recent consensus statements highlights on the importance of new predictive biomarkers of ICIs-mediated cardiotoxicity (12, 13). Indeed, echocardiographic biomarkers such as changes in global longitudinal strain (GLS) (12), or myocardial work (MW) (13) or increases in plasma levels of galectin-3 and cytokines (14) are of great interest in clinical cardioncology. Considering that Pembrolizumab and Ipilimumab recognize both human and mice PD-1 and CTLA-4 epitopes (15, 16), we have highlighted on the vascular and myocardial inflammation in female mice through immunohistochemistry and ELISA methods shedding light on potential pathways involved in ICIs cardiotoxicity, including NLRP3, MyD88 and DAMPs.

## Materials and methods

### Cell cultures

Human cardiac cells (HFC cell line; Innoprot, Derio, Spain) were cultured following the manufacturer's instructions (17, 18). Culture medium was supplemented with Fetal Bovine Serum at 10% v/v (FBS, Sigma Aldrich, St. Louis MO, USA), Penicillin at 50 U/ml, Streptomycin at 50 µg/mL and L-Glutamine at 1% v/v.

### *In vitro* cytotoxicity assays and cardiac cell lysis

Considering that PD-1 and CTLA-4 are expressed in human cardiomyocytes, as recently analyzed by our group through cell ELISA assays on human fetal cardiomyocytes with anti-PD-1 and anti-CTLA-4 mAbs (19), Ipilimumab and Pembrolizumab were added to HFC cells co-cultured with human lymphocytes. In brief, cells were plated in 96-well flat-bottom plates (at 10,000 cells/well) for 16 h. Human Peripheral Blood Mononuclear Cells (hPBMCs) were added at effector: target ratio 5:1 in the absence or presence of the mAbs (200 nM), and incubated for 24 h at 37°C, as previously described (20). Cells un-incubated or incubated with aspecific antibodies IgG were defined as control. After treatment with antibodies, lymphocytes were removed and adherent cells were washed and counted through trypan blue method. Lymphocytes can be easily removed by collecting the supernatant of co-cultures and by washing the tumor adherent cells as the lymphocytes are non-adherent. Cell survival was expressed as percent of viable cells tested with drugs compared to the untreated ones, used as a negative control. Cardiac cell lysis was determined as described in other recent work (21, 22) through the quantification of released LDH (LDH detection kit, Thermo-Fisher Scientific, Meridian Rd., Rockford, IL USA), following the manufacturer's instructions.

### ELISA assays on mouse purified proteins and PBMCs

The Enzyme-linked immunosorbent assay (ELISA) was performed on mouse PBMCs and purified recombinant target proteins to test the human-mouse cross-reactivity of the antibodies. Mouse lymphocytes ( $4 \times 10^5$  cells/well) activated with anti-CD3/CD28 beads for 3 days were plated on round-bottom 96-well plates. The purified recombinant human or mouse CTLA-4/Fc or the Fc portion (used as a negative control) were coated on flat bottom plates and blocked with a buffer solution (PBS/milk 5% v/v) for 1 h. The plates were incubated with increasing concentrations of antibodies in a buffer solution (PBS/milk 2.5% v/v) for 2 h. After washing, plates were incubated with HRP-conjugated anti-human IgG (Fab')<sub>2</sub>

goat monoclonal antibody in a buffer solution (PBS/BSA 3% v/v) for 1 h. The following steps were performed as previously described (23). The Absorbance values at 450 nm were measured by an Envision plate reader (Perkin Elmer, 2102, San Diego, CA, USA).

### Animal studies

Twenty four C57Bl/6 mice (female, 6 weeks/age) were purchased from Harlan, San Pietro al Natisone (Italy). As standard protocol, firstly mice were housed and maintained on a 12 h light-12 h dark cycle in a room with a fixed temperature of 22°C with the appropriate foods water. The experimental protocols were approved by the Ministry of Health with authorization number 1467/17-PR of 13-02-2017, and institutional ethics committees: Organismo preposto al benessere degli animali (OPBA) in accordance with EU Directive 2010/63/EU for animal experiments and Italian D.L.vo 26/2014 law. Briefly, animals were randomly divided into three groups (6 mice per group) as followings:

- Control group: mice daily received normal saline injection (by i.p) every three days for 10 days
- Ipilimumab group: mice received a short therapy with a CTLA-4 blocking agent (Bristol-Myers Squibb, Princeton, New Jersey, US) (15 mg/kg/day by i.p) every three days for 10 days;
- Pembrolizumab group: mice received a short therapy with a PD-1 blocking agent (Merck & Co., Inc., Kenilworth, NJ, USA) (15 mg/kg/day by i.p) every 3 days for 10 days.

Notably, every drug was used in the clinically available formulation. The injected dose of 15 mg/kg mean body-weight was comparable to the uses of ICIs in clinical oncology (16, 17, 24–26); moreover, the dose used is within the range of doses administered intraperitoneally (1–30 mg/kg) in preclinical models for pharmacokinetic studies and anticancer studies with ICIs (15, 27, 28).

### Echocardiographic evaluation of ventricular functions

To assess cardiac functions, the transthoracic echocardiography method was made in mice by using the Vevo 2100 (40-MHz transducer; Visual Sonics, Toronto, ON, Canada) which allows the determination of different cardiac function parameters in anesthetized mice (18, 29, 30). In brief, before (T0), after three days (T3) and at the end of treatments (T10) mice were prepared for cardiac function assessment by previous anesthesia through a solution composed by tiletamine zolazepam (both at 0,09 mg/g of weight) and atropine (at 0,04 mL/g of weight). The left

FIGURE 1

Binding assays of Pembrolizumab and Ipilimumab on mouse PBMCs and on human and mouse purified recombinant target proteins. ELISA assays were performed by using the indicated antibodies at increasing concentrations on mouse (black bars) CTLA-4/Fc or PD-1/Fc (A,B). The binding of antibodies was also tested on the Fc portion (empty bars), used as a negative control. Cell ELISA assays were performed by testing Pembrolizumab (C) ( $n = 3$ ) or Ipilimumab (D) ( $n = 3$ ) on mouse PBMCs untreated or activated with anti-CD3/CD28 beads. (E) LDH assay on the supernatant of co-cultures of HFC and hPBMCs treated as indicated ( $n = 3$ ). Cell lysis was measured as described in the materials and methods section. Error bars depict means  $\pm$  SD.

ventricular echocardiography was performed in parasternal long-axis views (with a frame rate corresponding to 233 Hz). Firstly, in M-mode assessment, the left ventricular internal dimensions in diastole and a systole (LVID<sub>d</sub>; LVID<sub>s</sub>) were calculated from 3 to 5 beats. Fractional shortening and ejection fraction percentage (both in percentage) were

determined as described in other recent work (15). Moreover, radial (RS, corresponding to the change in myocardial wall thickness) and longitudinal strain (LS, percent change in length of the ventricle) were calculated on long-axis views following the guide instructions of the Vevo 2100 software (15, 29).

**FIGURE 2**  
**(A)** DAMPs, including fibronectin, **(B)** S100 calgranulin, **(C)** galectin-3, and **(D)** cytokines and growth factors produced by cardiomyocytes in the supernatant of co-cultures of cardiomyocytes with hPBMC. The cytokines IL-1 $\alpha$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-10, IL-12, IL17- $\alpha$ , IFN- $\gamma$ , TNF- $\alpha$ , G-CSF, GM-CSF ( $n = 3$ ) were quantified by ELISA assays. Error bars depict means  $\pm$  SD.

## Myocardial inflammation and DAMPs expression

After treatments, mice were anesthetized as described in section echocardiographic evaluation of ventricular functions and sacrificed via cervical dislocation. Hearts were excised, washed three times in physiological solution (to eliminate blood residues), weighed and divided into two parts through a proper longitudinal cut. One half was used for biochemical studies and the other part to histological analyzes. Firstly, hearts were lysed under ice in a lysis solution consisting of Triton  $\times$  100 1% V / v spiked with a protease inhibitor. To promote lysis, tissues were treated with ultrasounds for 5 min. After centrifugation at 4°C at 1,300 rpm for 10 min,

the supernatant of the cardiac homogenates were used to quantitative analysis of six biomarkers of cardiac damages and inflammation, such as: myeloid differentiation primary response 88 (MYD-88) expression (through mouse MyD88 ELISA Kit (My Biosource, San Diego, CA, detection range of 78–5,000 pg/ml; sensitivity: 46.9 pg/ml); NOD-, LRR- and pyrin domain-containing protein 3 (NLRP-3) (through mouse NLRP3 ELISA Kit (OKEH05486, Aviva Systems Biology); Fibronectin-EDA, S100/Calgranulin and Galectine-3 [three DAMPs (quantified in cardiac tissues through selective quantitative assay); twelve cytokines and growth factors (IL-1 $\alpha$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-10, IL-12, IL17- $\alpha$ , IFN- $\gamma$ , TNF- $\alpha$ , G-CSF, GM-CSF) through a mouse cytokine Multiplex Assay kit (Qiagen, USA, pg/mg of heart tissue).

FIGURE 3

Cardiac function studies. Before (T0), after 3 days (T3) and at the end of treatments (T10) with saline or Ipilimumab or Pembrolizumab (15 mg/kg/die), cardiac functions studies were performed. Ejection fraction (%) ( $n = 6$ ), fractional shortening (%) ( $n = 6$ ), radial ( $n = 6$ ) and longitudinal strain (%) ( $n = 6$ ) were analyzed through VEVO 2100 echocardiography. Error bars depict means ± SD.

## Systemic levels of SDF-1 (CXCL-12), IL-1 $\beta$ , IL-6

For systemic analysis, blood samples were collected in three points: before (T0), after three days (T3) and at the end of treatments (T10) in heparinised tubes and immediately centrifuged at 3,000 rpm for 10 min at 4°C in order to obtain plasma that was collected, frozen, and kept at −80°C until use. Circulating SDF-1 (CXCL-12), IL-1 $\beta$ , IL-6 were quantified in 0.1 mL of plasma through the use of mouse CXCL12/SDF-1 alpha Quantikine ELISA Kit (MCX120, R&D Systems, Minneapolis, MN, USA), mouse IL-1 $\beta$  ELISA kit (BMS6002, Thermo Fisher, Milan, Italy) and mouse IL-6 ELISA kit (KMC0061, Thermo Fisher, Milan, Italy).

## Histology

Blinded histological examination of myocardial tissues were also performed. All selected samples were fixed in formalin and embedded in paraffin. Firstly, tissues were deparaffinized in a solution of xylene and rehydrated through graded alcohols. Antigen retrieval was performed with slides heated in 0.01 M edta buffer (pH 8.0.) for 10 min at 110 °C. Slides were rinsed with TBS and treated with a solution at 3 % v/v hydrogen peroxide. Another washing in BSA 5% v/v in PBS was performed as blocking step and an incubation for 12h with a primary antibody (diluted 1:100 in PBS) against mouse NF- $\kappa$ B (Abcam, Cambridge, UK) was performed. Sections were incubated with goat anti- anti-rabbit secondary IgG biotinylated secondary antibody for 0.5h. Tissue reactivity was determined through the avidin-biotin-peroxydase method (Novocastra, Newcastle, UK) as described in other work (30). After, sections were counterstained with haematoxylin. To determine the structure of the heart, and to evaluate parameters such as hypertrophy, necrosis and fibrosis, the tissues of the heart were incubated with Mayer's hematoxylin for 30 s and washed properly with water (30). Antigen expression was evaluated by one experienced pathologist by using light microscopy. For NF- $\kappa$ B nuclear localization in vascular endothelium of the murine tissues under examination was considered. Immunostaining values were reported as percentage of positive cells in 10 non-overlapping fields by using magnification X400 (31).

## Statistics

Data are presented as means  $\pm$  standard errors (SE). All data were tested for normality by Shapiro-Wilk. Normally distributed data in two groups were tested with Student's *t*-test, and non-normally distributed data in two groups by Wilcoxon-Mann-Whitney. Normally distributed data in multiple groups were tested by one-way analysis of variance (ANOVA) with Sidak correction. Non-normally distributed data were tested by

ANOVA with Holm-Sidak post-testing. Paired data were tested using the paired versions of *t*-Student.

## Results

### Pembrolizumab and Ipilimumab recognize and bind mouse PD-1 and CTLA-4 and induce cardiotoxic effect in human cardiomyocytes

We first verified the immunoreactivity of Pembrolizumab and Ipilimumab compared to murine epitopes of PD-1 and CTLA-4, respectively, through ELISA binding assays. As specified in Figure 1, and in line with other recent research (15, 22), Pembrolizumab and Ipilimumab are both able to bind to the mouse targets even though the affinity is lower than that observed for their human counterparts. Cardiotoxicity of Pembrolizumab and Ipilimumab in human *in vitro* models of co-cultures of hPBMC and human cardiomyocytes. To confirm in a human-like environment the results obtained in mouse models on the cardiotoxic effects of the immunomodulatory mAbs, we tested their effects in *in vitro* human models based on co-cultures of human cardiomyocytes (HFC) and lymphocytes. As shown in Figure 1, three mAbs induced a significant cardiac cell lysis (up to 50% for Pembrolizumab), thus indicating that they can indeed activate immune responses against cardiac cells.

### ICI treatment promotes DAMPs and pro-inflammatory cytokine production in co-cultures of hPBMCs and human cardiomyocytes

It was verified if ICIs could affect the production of DAMPs, pro-inflammatory cytokines, chemokines, and growth factors in co-cultures of human cardiomyocytes with human peripheral blood mononuclear cells (hPBMCs) by analyzing the supernatant by ELISA assays. Firstly, in a similar fashion to the *in vivo* findings, all ICIs increased the production of Fibronectin-EDA (Figure 2A), S199/Calgranulin (Figure 2B) and Galectine-3 (Figure 2C) compared to untreated cells. However, the analysis of cytokines secretion indicated that only IL-1 $\alpha$ , IL-1 $\beta$ , IL-6, and TNF- $\alpha$  were significantly increased after incubation with ICIs (Figure 2D).

### Short-term ICI therapy reduces radial/longitudinal strain and ejection fraction

We determined the cardiotoxic effects of PD-1 and CTLA-4 blocking agents in C57Bl/6 mice through the study of FS, EF,

RS, and LS by using two-dimensional echocardiography (Vevo Strain 2100, Fujifilm). Analysis of EF and FS indicated that short term of ICIs therapies significantly reduces the cardiac function (Figure 3). No differences were seen between groups. Instead, more significant reductions were observed for radial and longitudinal strain in ICIs groups vs. control. Again, no differences between the ICIs were seen (Figure 3).

### Short-term ICI therapy increases vascular expression of nuclear factor kappa-light-chain-enhancer of activated B cells (NF- $\kappa$ B)

Analysis of vascular and myocardial NF- $\kappa$ B expression shows that short-term anti-CTLA-4 or anti-PD-1 treatment had differential effects (Figure 4). However, first, both ICIs increased significantly the vascular inflammation compared to untreated mice but the higher NF- $\kappa$ B expression was seen in Pembrolizumab compared to Ipilimumab group (Figure 4A). Histological characterization of the myocardial tissue phenotype confirms no detectable vascular NF- $\kappa$ B expression in untreated mice (Figure 4B) but a strong vascular expression was seen in ICIs groups (see arrows in Figures 2C,D).

### Short-term Pembrolizumab therapy increases cardiac hypertrophy

Morphological characterization of the myocardial tissue phenotype in mice after short-term anti-CTLA-4 or anti-PD-1 treatment clearly indicates no cardiac hypertrophy with the exception of Pembrolizumab (Figure 5). Compared to control (sham), ematoxylin-eosin staining of longitudinal sections of mice treated with Ipilimumab did not show any significant hypertrophy; cardiomyocytes have a linear and homogeneous longitudinal aspect, the nucleus is not pycnotic and has a regular size and shape, and there are no cytoplasmic vacuoles. On the other hand, the cardiac longitudinal section of mice treated with Pembrolizumab shows a significant hypertrophy with evident increases in the cytoplasmic volume and an irregular course of the cardiomyocytes (Figure 5).

### Short-term ICI therapy increases cardiac fibrosis and myocardial expression of MMP-9, Galectin-3, and pro-collagen- $\alpha$ 1

Histological characterization of the myocardial tissue phenotype in mice after short-term anti-CTLA-4 or anti-PD-1 treatment showed that ICIs increased cardiac fibrosis compared to untreated mice (Figures 6A–C). In control group (Figure 6A) hematoxylin-eosin staining of longitudinal sections evidenced the absence of fibrosis, whereas treatment with Ipilimumab or Pembrolizumab (Figures 6B,C) increased drastically the fibrotic phenotype. Myocardial expression of galectin-3 (Figure 6D), mouse pro-collagen 1- $\alpha$  (Figure 6E) and MMP-9 (Figure 6F), biomarkers of fibrosis, corroborates these findings: galectin-3 is almost undetectable in control group while it is drastically increased after treatment with all ICIs ( $1.7 \pm 1.2$  vs.  $24.5 \pm 4.2$  vs.  $32.3 \pm 4.3$  ng/mg of tissue for control, Ipilimumab and Pembrolizumab, respectively;  $p < 0.001$  for control vs. ICIs). Similar results were seen for procollagen 1 $\alpha$ 1 ( $3.4 \pm 1.2$  vs.  $15.3 \pm 3.1$  vs.  $16.8 \pm 1.2$  ng/mg of protein for control, Ipilimumab and Pembrolizumab, respectively;  $p < 0.005$  for control vs. ICIs) and MMP-9 ( $407.8 \pm 89.6$  vs.  $732.5 \pm 102.2$  vs.  $895.5 \pm 88.6$  pg/mg of protein for control, Ipilimumab and Pembrolizumab, respectively;  $p < 0.05$  for control vs. ICIs).

### ICI therapy promotes DAMPs production, NLRP3, and MyD88 expression in myocardial tissues

We investigated on cardiac markers of inflammation and cell damages (DAMPs). Compared to untreated mice, ICIs increased significantly Fibronectin-EDA expression (Figure 6G) in heart lysates ( $2.3 \pm 0.16$  for Ipilimumab and  $2.1 \pm$

FIGURE 5

Hypertrophy analysis in myocardial tissues of mice treated with ICIs. (A) Hematoxylin-eosin staining of longitudinal sections with no hypertrophy in control untreated mice ( $\times 40$ ); (B) hematoxylin-eosin staining of longitudinal sections with no hypertrophy in untreated mice and mice treated with Ipilimumab ( $\times 40$ ); (C) hematoxylin-eosin staining of longitudinal sections highlights the development of marked hypertrophy in mice treated with Pembrolizumab ( $\times 40$ ).

0.25 for Pembrolizumab;  $p < 0.001$  for control vs. ICIs). Similarly another DAMP, called S100 Calgranulin (Figure 6H) was significantly enhanced by ICIs treatment ( $1.86 \pm 0.21$  for Ipilimumab and  $1.96 \pm 0.24$  ng/mg of protein for Pembrolizumab;  $p < 0.001$  for control vs. ICIs); no significant differences between ICIs were seen. Inflammasome and myddosome complex stimulates DAMPs, therefore, myocardial expression of NLRP type 3 and MyD type 88 were analyzed. A drastic increase in MyD-88 expression (Figure 6I) ( $33.2$  pg/mg of protein  $\pm 15.6$  for untreated mice;  $198.6 \pm 18.3$  for Ipilimumab;  $217.5 \pm 17.4$  for Pembrolizumab;  $p < 0.005$  for ICIs vs. control). The same behavior was seen for NLRP3 expression after treatment with all ICIs ( $47.3$  pg/mg of protein  $\pm 13.5$  for untreated mice;  $132.1 \pm 15.1$  for Ipilimumab;  $126.6 \pm 11.2$  for Pembrolizumab;  $p < 0.005$  for ICIs vs. control) (Figure 6J).

## ICI therapy increases pro-inflammatory cytokine expression in myocardial tissues

Cytokines and chemokines are drivers of anticancer drug-induced cardiotoxicity, heart failure and myocarditis (32). Therefore, cytokines and chemokines in heart tissue of Ipilimumab or Pembrolizumab-treated female C57Bl6 mice were quantified (Figure 6K). Firstly, the family of IL-1 cytokines (IL-1 $\alpha$  and IL-1 $\beta$ ), increased in all ICIs treated group with

respect to untreated mice ( $p < 0.001$ ). IL-2 levels were also increased in ICIs group, highlighting immune-related reactions in myocardial tissue. Anti-inflammatory cytokines levels (IL-4 and IL-10) were reduced in ICIs group vs. untreated mice. Other pro-inflammatory cytokines (IL-6, IL17- $\alpha$ , IFN- $\gamma$ , and TNF- $\alpha$ ) were also increased in myocardial tissues of ICIs-treated mice vs. saline-treated groups. Levels of growth factors involved in heart failure and hypertrophy (G-CSF and GM-CSF) were also increased in ICIs groups (Figure 6K).

## ICI therapy increases systemic levels of SDF-1 (CXCL12), interleukin-1 $\beta$ , and interleukin-6

High plasma levels of Stromal Cell-Derived Factor 1 (SDF-1), IL-1 $\beta$  and IL-6 were associated to cardiac inflammation, heart failure and cardiovascular mortality (33). We analyzed if short term ICIs therapy could affect SDF-1, IL-1 $\beta$  and IL-6 levels in plasma of C57/Bl6 mice (Figure 7). Before (T0), after three days (T3) and at the end of treatment (T10), systemic levels of all biomarkers were significantly increased with respect to control saline-treated mice ( $p < 0.05$ ). For example, after 10 days of therapy, SDF-1 levels were  $0.96$  ng/ml  $\pm 0.24$  for untreated mice;  $2.75 \pm 0.34$  for Ipilimumab and  $3.16 \pm 0.29$  for Pembrolizumab ( $p < 0.005$  for ICIs vs. control). The same behavior was seen for

FIGURE 6

Histological analysis of the hearts of mice untreated or treated with ICIs. (A) Hematoxylin-eosin staining of longitudinal sections in control untreated mice (x40); (B) hematoxylin-eosin staining of longitudinal sections in mice treated with Ipilimumab (x40); (C) hematoxylin-eosin staining of longitudinal sections with fibrosis in mice treated with Pembrolizumab (x40). (D) Cardiac expression of galectin-3 (ng/mg of tissue), (E) mouse pro-collagen 1- $\alpha$  (ng/mg of total protein), (F) MMP-9 (pg/mg of protein), (G) Fibronectin EDA (fold of control), (H) S100 Calgranulin (ng/mg of protein in myocardial tissue lysate), (I) MyD-88 (pg/mg of protein in myocardial tissue lysate) and (J) NLRP-3 (pg/mg of protein in myocardial tissue lysate) after short-term treatment with ICIs. In (K), Twelve cytokines (IL-1 $\alpha$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-10, IL-12, IL-17 $\alpha$ , IFN- $\gamma$ , TNF- $\alpha$ , G-CSF, GM-CSF) were analyzed in heart lysates and reported as pg of cytokine normalized for mg of tissue. Error bars depict means  $\pm$  SD (n = 6).

IL-1  $\beta$  and IL-6, indicating a systemic inflammation even after 3 days of treatment with ICIs (Figure 7).

## Discussion

The current study aimed to evaluate the pro-inflammatory effects of short-term immune checkpoint inhibitors (ICIs) treatment in myocardial and vascular tissues in preclinical models (34, 35) (Figure 8). Notably, the use of ICIs in clinical oncology found significant clinical benefits in cancer patients, however, a wide spectrum of side effects are being seen (called irAEs): rash (maculopapular, lichenoid), diarrhea, colitis, mucositis, hypo or hyper thyroidism, hepatitis, inflammatory arthritis, myalgia (36). Endocrinopathies and inflammatory pathologies induced by PD-1 / PDL-1 or CTLA-4 blocking agents are frequently reported in both monotherapy and combinatorial therapies. Clinical studies report both short-term and long-term side effects in cancer patients and the mechanisms are not yet well-known (37). There are both immune-mediated and non-immune-mediated mechanisms involved in irAEs. A recent meta-analysis reports a high incidence of myocarditis (about 11 times higher than in other therapies) which reaches a mortality rate of about 50% in case of combination therapies (PD1 / PDL-1 associated to CTLA-4 blocking agents) (38, 39). Furthermore, ICIs have recently been shown to accelerate the process of atherosclerosis in both preclinical and clinical study models. Even just a short treatment with ICIs increases the inflammatory state in the vascular endothelium by accelerating the atherosclerotic process

(39). Other recent studies show that short ICIs treatments can cause arrhythmias, Takotsubo syndrome and inflammatory vascular events (40, 41). Current data regarding ICIs-associated pericardial involvement are limited, but case-reports include pericarditis, pericardial effusion (42, 43). Notably, a deep knowledge of ICIs-induced myocardial injuries is needed. Immune cells uptake and infiltration in myocardial tissue were always seen in human histological studies (CD4, CD8 T cells and macrophages). Immune-related side effects involves several chemokines like CXCR 10, 9 and 3, high levels of granzyme B especially in myocardial tissue (44). Our data suggest that NLRP3 and MyD88 pathways could contribute to the increased vascular and myocardial inflammation of anti-CTLA-4/anti-PD-1 treatments. NLRP3 drives cytosolic damages, hypertrophy and inflammation through cytokines and overproduction of hs-CRP.

As described in Figure 6 and summarized in Figure 8, our data confirms that ICIs increases DAMPs in cardiomyocytes and myocardial tissue of mice models. It has been described that in patients with unstable angina or with AMI, endogenous DAMPs like Fibronectin-EDA, S100/Calgranulin, Galectine-3 are released from damaged cardiac cells and signal through TLR receptors. There is also emerging evidence for the involvement of Toll-like receptors type-9 in heart failure, which can be activated by endogenous DAMPs, including mitochondrial DNA, to modulate the progression of the disease (45, 46). The increases in DAMPs levels after short-term ICIs treatment in mice indicates myocardial injuries (46). Whether long-term ICI therapy affects myocardial stress and vascular inflammation is unknown. Nevertheless, our data suggest that even short-term

ICIs therapy induces vascular inflammation, fibrosis and levels of myocardial NLRP3 and MyD88 (Figure 8). Whether ICIs-induced inflammation persist after cessation of the therapy and how they affect myocardial work in the long-term is not currently known (47).

This work has several limitations: firstly, the use of a tumor-free mice model. As cardiovascular diseases and cancer share many pathophysiological pathways, including inflammation, the use of a tumor-bearing model would have increased the translational potential of our study. Moreover, there are clinical evidences that combination ICIs-therapy exerts the most frequent and pro-inflammatory cardiac and endocrine side effects compared to monotherapies (48) therefore, further cardiotoxic studies in preclinical models will be performed after the combination of anti-CTLA4 and anti-PD-1/PD-L1.

Another limitation is based on the short period of treatment with ICIs without a longer follow up. In real world clinical experience, cancer patients experienced ICIs-mediated side effects also many months after therapy cessation (47, 49). These effects could be also partially related to endocrine changes due to PD-1/CTLA-4 blocking pathways that exerts a detrimental cardiotoxic effects in these patients. Therefore, further preclinical studies on long-term cardiovascular side effects after ICIs therapy will be performed.

Another methodological limitation of this work is the absence of a more proper control group in animal studies based on the administration of IgG control antibody, however, as reported in cellular experiments (Figure 8), any changes in pro-inflammatory and cell dead markers were seen after incubation with control IgG. Moreover, it is plausible that the intraperitoneal administration of nonspecific IgG as a control

does not change neither cardiac functions nor cardiac and systemic inflammatory status in mouse models as confirmed by recent similar research papers (50, 51).

In conclusion, cardiotoxicity, although rare, is a clinically relevant problem in cancer patients undergoing ICIs. Long-term side effects of ICIs are reported, however, some biochemical changes may occur even a few days after treatment with ICIs, as specified in this work. The involvement of NLRP3 MyD-88 and some DAMPs in ICIs-associated cardiovascular disease was seen. Relevant histological effects such as cardiac endothelial inflammation and overexpression of pro-fibrotic and pro-inflammatory cytokines is a non-negligible fact that deserves further investigation. The increase in systemic levels of SDF-1, IL-1 $\beta$  and IL-6 indicates systemic pro-inflammatory effects induced by ICIs that can directly and indirectly increase the risk of myocarditis, however more detailed studies on the mechanisms of systemic and direct cardiac toxicity will have to be carried out. Of note, considering that PD-1 and CTLA-4 blocking agents recognize the murine epitope with lower affinity than the human epitope, the effects observed in this work could also be underestimated (12) consequently, short and long term clinical studies during ICIs deserve urgent investigation. Moreover, the results of this study warrant further preclinical cardioprotective trials with anti-cytokine (52, 53), anti-NLRP3 (54–56) or anti-MyD88 (57, 58) therapies in primary or secondary prevention of ICIs-related cardiotoxicity.

This study suggests that short-term ICI therapy affects myocardial and vascular inflammation through DAMPs and cytokines through NLRP-3 and MyD-88 related pathways (Figure 8). It is plausible that ICIs exerts both systemic and cardiac toxicities through the activation of cytokines cascades that exacerbate the inflammatory damages in cardiomyocytes. These results are in line with another recent work (59) demonstrating pro-atherosclerotic effects of short-ICIs therapy in mice models. Clinical studies are required to elucidate the effects of ICIs on myocardial and vascular inflammation and confirms the role of NLRP3 and Myd88 in progression of ICIs-mediated cardiovascular diseases.

## Data availability statement

The data presented in the study are deposited in the Zenodo repository, accession number <https://zenodo.org/record/7040431#.YyMLcYrP1D9>.

The cardiotoxicity of fluoropyrimidines (FP) [5-Fluorouracil and Capecitabine] is often reported as acute cardiac ischemia with rest typical angina, signs of ischemia at electrocardiogram (ECG), and ventricular kinetics abnormalities. However, silent ischemia, effort-related toxicity, and ventricular arrhythmias (VA) have been also described. The aim of this study is to report a consecutive series of 115 patients with FP cardiotoxicity observed in a single center both within clinical prospective studies and during the clinical routine. The clinical presentation widely varied as regards symptoms, ECG abnormalities, and clinical outcomes. We report also the strategies used to prevent cardiotoxicity in a subgroup of 35 patients who continued or rechallenged FP therapy after cardiotoxicity. In nearly half of the patients, the cardiotoxicity was triggered by physical effort. Typical angina was rare: the symptoms were absent in 51% of cases and were atypical in half of the other cases. ST-segment elevation and VA were the most frequent ECG abnormality; however, ST segment depression or negative T waves were the only abnormalities in 1/3 of the cases. Troponins essays were often within the normal limits, even in presence of extensive signs of ischemia. The most effective strategy to prevent cardiotoxicity at rechallenge was reducing FP dosage and avoiding physical effort. Anti-ischemic therapies were not always effective. Raltitrexed was a safe alternative to FP. Fluoropyrimidine cardiotoxicity shows a wide variety of clinical presentations in real life, from silent ischemia to atypical symptoms, acute coronary syndrome, left ventricular dysfunction (LVD), VA, or complete atrio-ventricular block. Physical effort is the trigger of cardiotoxicity in nearly half of the cases. The recognition of cardiotoxicity cannot rely on symptoms only but requires an active screening with ECG and stress test in selected cases.

## KEYWORDS

cardiotoxicity, cardiotoxicity after chemotherapy, capecitabine, fluorouracil/adverse effects, fluoropyrimidine chemotherapeutics, fluoropyrimidine cardiotoxicity, 5-fluorouracil, capecitabine cardiotoxicity

## Background

The fluoropyrimidines (FP) 5-fluorouracil (5-FU) and its prodrug capecitabine represent a mainstay of chemotherapy (CT) regimens for different types of malignancies, including head/neck, gastrointestinal, liver, and breast cancer. They can both induce cardiac toxicity (TOX), mostly in the form of myocardial ischemia (MI), ventricular arrhythmias (VA), left ventricular dysfunction (LVD), and sudden death (SD) (1–7). TOX of FP can be precipitated by effort and it can be asymptomatic, thus leading to an underdiagnosis in retrospective studies (8, 9). According to the literature, the most frequent clinical presentation of FP cardiotoxicity is angina with ST-segment elevation detected at Electrocardiogram (ECG) and mimicking vasospastic angina (Table 1). However, some prospective studies with Holter monitoring have reported transient asymptomatic ST segment elevation and ECG abnormalities different from ST-segment elevation have also been described (mostly ST segment depression and negative T waves) (10). A recent review analyzing data from 37 papers including the original data, reported wide variability in clinical presentation and risk factors, probably attributable to the different definitions provided for TOX and to the different modalities of data collection (11).

## Aim of the study

To describe the clinical presentation of FP cardiotoxicity in patients treated with FP in a single Institution: CRO, National Cancer Institute of Aviano (PN, Italy) from 2001 to 2021, and to report the possibility of cardioprotection strategies in a group of patients who underwent a rechallenge therapy with FP after the first episode of cardiotoxicity.

## Materials and methods

We searched the electronic database of the Cardiology Unit of the CRO from 2001 to 2021 and identified 141 patients who had been classified as having had FP cardiotoxicity. The clinical cardiologic and oncologic charts were reviewed by expert cardio-oncologists, in order to confirm the diagnosis and to collect data regarding the clinical history (before and after the diagnosis) whenever available. FP cardiotoxicity was defined as the presence of clinical, ECG, and/or echocardiographic signs of ischemia, Lown  $\geq 2$  VA, supraventricular arrhythmias, complete atrio-ventricular block, or LVD.

Symptoms were classified as follows: “typical chest pain” included typical angina (retrosternal constrictive or squeezing chest pain, radiated or not to the left arm or to jaws) and weight over the sternum; “atypical chest pain” included less defined chest pain or discomfort, burning sensation; “atypical symptoms” included jaw pain, throat constriction, malaise, dizziness, dyspnea.

The diagnosis of TOX had to be confirmed by the disappearance of clinical and instrumental abnormalities after withdrawing FP and by the exclusion of other causes of ischemia or arrhythmias.

After revision, 10 patients were excluded because the clinical diagnosis of cardiotoxicity was equivocal and another 26 patients (including two patients who died suddenly at home at the end of the 5-FU infusion) were excluded because it was not possible to collect detailed information about the ECG and the cardiovascular risk factors. The remaining 115 pts (74 males and 41 females, aged 19 to 79, mean  $59 \pm 11$ , median 61) are the object of our study (Figure 1). The cases had been observed both in daily practice and in two prospective studies where an effort stress test (EST) was obtained during FP treatment. We investigated also the clinical course of the patients in whom FP, after an episode of cardiotoxicity, was not discontinued or was later re-introduced in the therapy.

## Results

Amongst the 115 patients evaluated in the present study, 79 had at least one CVRF, 15 had a clinical history of ischemic heart disease and 41 were on medical therapy with one or more cardiovascular drugs (in particular, 8 with calcium-channel blockers, 11 with beta-blockers, 22 with angiotensin-converting enzyme inhibitors, and 9 with nitrates). The FP administered was 5-FU in 64 patients and capecitabine in the remaining 51 patients (Table 2).

Cardiotoxicity (Table 3) was observed at rest in 63 patients and during physical effort in 52 patients. Furthermore, effort-related symptoms during daily life were reported by 10 patients who had cardiotoxicity confirmed by the EST. The ECG recorded at the time of cardiotoxicity diagnosis showed ischemic repolarization changes in 96 patients: ST-segment elevation (1 to 7 mm) in 53 patients, ST segment depression (1 to 7.5 mm) in 16, both ST-segment elevation and depression in 12 patients; negative T waves only in 15 patients. The number of ECG leads showing ST-T changes of ischemia ranged from 2 to 12 (median 5).

Arrhythmias were observed in 34 patients: in particular, 28 patients had ventricular ectopic beats and another 6 patients experienced other kinds of arrhythmias (supraventricular tachycardia, severe bradycardia, and atrio-ventricular block).

Typical angina was complained by 32 patients, atypical precordial pain, chest discomfort, or epigastric pain (suggestive of angina equivalents) were reported by 21 patients and other atypical symptoms (dyspnea, sore throat, jaw pain, palpitation, dizziness, and syncope) were instead experienced by 11 patients. Noteworthy, 51 patients were completely asymptomatic, and the diagnosis was made based on ECG and/or echocardiographic changes. The correlations between symptoms, ECG signs of ischemia, and arrhythmias are described in Table 4.

FIGURE 1  
Selection of population reported in the study.

An echocardiogram was performed immediately at the time of detection of cardiotoxicity in 33 patients: it showed global or segmental kinetics abnormalities in 14 patients, while it was normal in the remaining 19 patients. Troponin was dosed in 28 patients and was above the normal limits of the laboratory in 8 cases.

After the diagnosis of FP cardiotoxicity, each patient was managed on an individual basis, according to the severity of toxicity, the stage of the neoplastic disease, and the availability of alternative treatments. The patients with acute coronary syndrome or severe arrhythmias were admitted to the Intensive Care Unit (ICU) and treated according to the best clinical practice. It is important to recall that uridine triacetate, which has been proven effective for severe FP toxicity, is currently not available for use in Italy (12, 13). The patients with minor signs or symptoms were either treated in the oncologic ward under cardiologic supervision or treated on an ambulatory basis. Cardiovascular therapy was prescribed according to the type of toxicity (MI, arrhythmias, LVD) and whether it occurred at rest or it was effort-related. If severe, even life-threatening toxicities (severe MI, arrhythmias, or LVD) occurred, or if the CT was considered avoidable (i.e., adjuvant treatment in patients with mild risk of relapse) or valid alternative regimens were available, FP-based CT was interrupted. In patients with minor toxicity or a strong indication to receive FP, the treatment was continued; in other patients, instead, it was interrupted but a rechallenge was attempted months or years later because of a relapse of the disease.

Overall, FP treatment was continued or re-introduced in 35 patients (Table 5). To prevent the recurrence of a cardiotoxicity event, several strategies (alone or in combination) were used: in 7 patients capecitabine was replaced by the 5-FU infusion

\* Arrhythmias observed during/after effort were ventricular arrhythmias in 26 patients (3 had also ST segment abnormalities), and complete atrio-ventricular block in one. Typical chest pain includes typical angina and oppressive chest pain.

lasting  $\leq 72$  h; in 9 patients the FP dose was reduced by 25–50%; in 22 patients anti-ischemic and/or antiarrhythmic drugs (nitrates, calcium channel blockers, beta-blockers, ranolazine, and trimetazidine) were added to the therapy. A second rechallenge with a different approach (increase of FP dose after a successful attempt of rechallenge, or a different drug) was attempted in 7 patients. All the patients with effort-induced cardiotoxicity were screened with physical stress test during the rechallenge. The characteristics of the patients, the strategies applied and the results are reported in **Table 5**. Within the 35 patients who underwent the first rechallenge, 6 had again a severe cardiotoxicity event and the treatment was definitively interrupted in 5 of them (one of these patients was shifted to raltitrexed which, like FP, belongs to the CT class of anti-metabolites), instead, 4 patients had milder cardiotoxicity (evident only during stress test) and continued the therapy avoiding any physical effort and, finally, 25 patients were able to tolerate the rechallenge. Cardiotoxicity was completely prevented in 5 of the 7 patients who had an FP dose reduction only, in 10 of the 13 patients which received FP with dose reduction and anti-ischemic therapy, and in 4 of those patients who received a full dose FP and anti-ischemic therapy. Also, 4

patients with mild or no toxicity who received FP at a lower dose, experienced more severe toxicity when the drug dose was increased again. The 3 patients who shifted to raltitrexed did not have any cardiovascular adverse events and tolerated 3, 4, and 28 CT courses, respectively.

## Discussion

In our experience, the clinical presentation of FP cardiotoxicity is extremely variable and often different from the classical description of “angina and ST-segment elevation at ECG,” which is typical of vasospastic angina.

More than one-third of our patients were completely asymptomatic and cardiotoxicity was identified on the basis of ECG changes. This prevalence of asymptomatic cases is much higher than the one reported in other retrospective studies but lower than the prevalence observed in the two prospective studies conducted in our Institution where all the patients without rest cardiotoxicity performed a stress test (14). Actually, this study includes the cases detected in the two prospective studies conducted in our Institution, in which

cardiotoxicity was actively searched for with EST, and also those observed during daily clinical practice. It should be considered that, after our first observations of effort-induced cardiotoxicity and of asymptomatic ischemia in 2001 (15), we started active surveillance of cardiotoxicity even outside the prospective studies and this raised our chances of detecting the cardiotoxicity in regular clinical practice. For all patients, we perform a routine baseline ECG before the beginning of the treatment, we plan a second one after 2–4 days of CT with 5-FU or after 7–14 days of CT with capecitabine whenever possible (i.e., patients receiving in-hospital CT, patients undergoing daily radiotherapy, patients living near the hospital) and we advise the patients undergoing FP-based CT to avoid any physical effort and to promptly refer any new symptom (as chest pain, jaw pain, dyspnea, and palpitations) occurring during therapy. When a new ECG abnormality is observed and/or a new symptom is reported, the patient undergoes a cardiologic evaluation including an echocardiogram and/or stress test, if necessary, to define the diagnosis. This approach has been demonstrated to be effective in detecting several asymptomatic or oligosymptomatic toxicities, probably missed by most of the retrospective studies published so far, which included only those patients with clinical symptoms referred to the caring oncologists (16). At the same time, by advising to avoid physical efforts, the probability of eliciting effort-induced cardiotoxicity (which, according to our prospective studies with EST, accounts for half of the cases of cardiotoxicity) is reduced.

Concerning the ECG abnormalities, about half of the patients evaluated in the present study had ST-segment elevation

(either alone or with specular ST segment depression), while other patients had negative T waves only or arrhythmias without typical ECG signs of ischemia. This contrasts with the hypothesis of vasospasm being the main cause of FP-related cardiotoxicity, which has been proposed for many years, and it is in support of multifactorial pathophysiology (17–21). Of note, ST-segment elevation was more frequent in the patients with rest cardiotoxicity, compared with those with stress-induced toxicity.

Other studies have reported retrospective or prospective series of FP-related cardiotoxicity, but it is not always easy to compare those data with ours, as the criteria for defining cardiotoxicity, and even the symptoms and the ECG changes, are equivocal.

In 1992, De Forni et al. prospectively studied 367 patients undergoing 96–120 h of 5-FU continuous infusion. Cardiotoxicity was observed in 28 patients (7.6%): 18 of them had angina, 12 presented cardiac collapse or pulmonary edema, and 8 patients died (5 suddenly and 3 of cardiogenic shock), ECG signs of ischemia were evident in 18 out of these 28 patients and global or segmental kinetics reduction was evident in 9 out of 16 patients who underwent an echocardiogram (22).

In a prospective study, Yilmaz et al. evaluated the role of Holter monitoring in 27 patients treated with 5FU: they did not observe any ST-T change (not even in the 2 patients who experienced chest pain); however, both a significant decrease in mean heart rate and an increase in the number of VA were reported (23).

5FU, 5 Fluorouracil; ASA, Acetylsalicylic acid; LVD, left ventricular dysfunction; \*, patients who had a second rechallenge with different approach.

Khan et al., in a 2012 retrospective study, reported 60 cases of “symptomatic cardiotoxicity” including 10 patients with not specified “ischemic ECG changes,” 10 with “chest pain,” 11 with ventricular tachycardia, 1 cardiac arrest, 36 with bradycardia, 18 with hypotension, 7 with hypertension, and 2 with atrio-ventricular block. The ECG repolarization abnormalities were described for 18 cases only: ST-segment elevation was detected in 5 patients, ST segment depression in 2 patients, and negative T waves in 11 patients (24).

Peng et al. (10) in 2018, published a multicentric prospective study evaluating data from 527 patients of which 161 experienced cardiotoxicity related to FP administration. In particular, 6 patients experienced a MI, 20 had heart failure (no cases of angina are reported) and 33 had “premature beats” (if ventricular or supraventricular is not specified). At ECG, a total of 105 “ischemic changes” were reported, including 70 “ST changes” and 47 “T wave changes”.

Instead, in a retrospective study by Zafar et al., only 5-FU-induced coronary vasospasm was considered and only a very low rate of cardiotoxicity was reported: although the occurrence of 5-FU-related cardiotoxicity was likely underestimated, this actually confirms our observation that typical vasospastic angina probably accounts for no more than 50% of the cases of FP cardiotoxicity (25, 26).

In a 2016 retrospective study, Dyhl-Polk et al. reported data from 452 breast cancer patients treated with capecitabine. In this study, a total of 22 cases of cardiotoxicity were diagnosed on the basis of the appearance of cardiac symptoms: chest pain in 11 patients, MI in 2 patients, arrhythmias in 5 patients (one had a cardiac arrest), and dyspnea in 3 patients (27). Two recently published studies (one retrospective and one prospective) by the same group gave results comparable to the ones obtained in our study. In the retrospective study, conducted on patients with colorectal cancer (of which 995 were treated by 5-FU and 1241 with capecitabine), 103 cases of FP-related cardiotoxicity were reported (5.2% in the 5-FU group and 4.1% in the capecitabine group). The ECG (not obtained for all patients) showed ST-segment elevation in 17 cases, ST segment depression or negative T waves in 9 and 8 cases, respectively, and VA in 6 cases. Regarding the symptoms, 45 patients had unstable angina, 23 patients experienced acute MI (10 cases with ST-segment elevation and 13 cases without ST-segment elevation), 10 patients had atypical symptoms (chest pain, dizziness, and dyspnea), 2 patients experienced a syncope secondary to atrio-ventricular or sino-atrial block and a total of 10 patients experienced sudden death or cardiac arrest (28). In the prospective study, instead, the same group of authors reported MI detected by ECG Holter in 20 patients receiving FP

(18.7% of the whole group), and 16 of these patients (15% of the whole group evaluated, 80% of those with signs of ischemia) had silent ischemia (29). Six patients (5.6% of the whole study group) developed an acute coronary syndrome (in 3 cases the symptoms had been preceded by silent ischemia recorded at Holter) and 2 patients had symptomatic VT; 1 patient had a cardiac arrest after cessation of 5-FU and Holter recording revealed an ST-segment elevation. These two studies confirm some of our observations: first of all, in FP-related cardiotoxicity, ST segment depression or negative T waves are as frequent as ST-segment elevation. Secondly, that silent ischemia is rather frequent and can precede significant clinical events, such as acute coronary syndrome and/or cardiac arrest. Finally, the detection of FP-related cardiotoxicity is more than doubled in prospective studies in which planned ECG screening is performed.

It should be considered that, in our study, 24 out of 31 patients complaining of typical angina and 8 out of 9 patients with chest pain, presented ECG signs of ischemia, mostly represented by ST-segment elevation (assessed in 18 and 6 patients, respectively). This might explain why, in the studies identifying cardiotoxicity on the basis of clinical symptoms, ST-segment elevation is the most frequent ECG abnormality.

Another peculiar observation in our experience is that 55% of the patients with effort-induced cardiotoxicity had VA, which may cause syncope or sudden death. This is the main reason why we are presently giving to all the patients beginning a CT with capecitabine the advice to avoid any unusual physical effort when on therapy.

Another peculiar finding in our experience is that 60% of the echocardiograms performed shortly after detection of the cardiotoxicity were normal; it should be considered, however, that both symptoms and ECG abnormalities may vary over time, and if the echocardiogram is not obtained during the acute episode it can be normal. Thus, a normal ECG and a normal echocardiogram in a patient who had reported angina symptoms during FP therapy but is presently asymptomatic cannot rule out the cardiotoxicity.

As regards the possibility that a dihydropyrimidine dehydrogenase (DPD) deficiency might have played a role in the cardiotoxicity of our patients, most of the cases had been observed before the routine use of the test in our Institution, and all those who were tested showed a wild-type gene. Thus, also a wild-type phenotype cannot exclude the possibility of cardiotoxicity. It should also be noted that the DPD polymorphism is a known risk factor for hematological and gastrointestinal, but not cardiac toxicity. (30, 31).

The rechallenge with the same drug after FP-induced cardiotoxicity poses a high risk of severe events and death; according to the suggestions provided by Saif et al., we limited the rechallenges to the patients with a strong indication of FP therapy and performed close monitoring with frequent ECG (or Holter monitoring), a close cardiologic follow-up and EST in selected cases (32, 33). The strategies employed to prevent cardiotoxicity when a rechallenge was considered necessary

were variable and depended upon the available knowledge on FP toxicity, the anti-ischemic drugs available at different times, and also to the compliance of the patients. In the first years, we used mostly nitrates and nifedipine, according to the hypothesis of vasospasm; diltiazem was the preferred calcium channel blocker after a report on its utility in a small series of patients (34); beta-blockers were used in those patients with VA as the main manifestation of cardiotoxicity, in those with underlying coronary artery disease and in those with typical angina but with no signs of vasospasm. However, many patients were hypotensive and did not tolerate calcium channels blocker or beta blockers and others did not tolerate nitrates because of the onset of headaches. In some cases, the therapeutic approach was modified several times, using a treadmill stress test to assess the efficacy of the preventive measures, always trying to maintain the best anti-neoplastic effect, as previously described (33). Ranolazine, introduced in clinical practice in recent years, was well tolerated and it was effective in 2 patients, but not in a third. The number of patients undergoing a rechallenge is too little to allow an analysis of the efficacy of different cardiovascular treatments. However, our data suggest that the reduction of FP dose (associated with an anti-ischemic treatment if tolerated) and the shift from capecitabine to 5-FU or to a less cardiotoxic drug as raltitrexed, is probably the best approach, as already reported by other studies (35–40).

Raltitrexed is a quinazoline inhibitor of the enzyme thymidylate synthase and it is employed in the treatment of advanced malignant pleural mesothelioma [in association with cisplatin it has been demonstrated to improve the overall survival (41)] and in the treatment of advanced colorectal cancer. In patients with advanced colorectal cancer, raltitrexed has failed in demonstrating a superiority, in terms of survival outcome, when compared to 5-FU, at the cost of a higher incidence of hematological and gastrointestinal toxicity (42). However, in patients with cardiotoxicity induced by 5-FU or capecitabine, raltitrexed can represent a valid alternative, given the better cardiovascular tolerability profile (40, 42).

S1, an oral fluoropyrimidine composed of tegafur (a 5-FU prodrug), gimeracil (a dihydropyrimidine dehydrogenase, DPD, inhibitor), and potassium oxonate, is employed in Asia and in some European Countries for the treatment of different kinds of solid tumors, including advanced colorectal cancer. Lower toxicity of S-1 in the cardiovascular system could be explained by the fact that gimeracil inhibits DPD, which degrades 5-FU into its main metabolite alpha-fluoro-beta-alanine (43) (FbAL). Muneoka et al., in fact, described the case of a patient that experienced a MI after 5-FU administration and in which high levels of serum FbAL were detected. This same patient was later treated with S-1 and did not experience any additional cardiotoxicity (44).

Uracil/Tegafur (UTF), which is an oral agent composed of tegafur and uracil, is employed in Asia and also in South America in patients with advanced colorectal cancer that have experienced a cardiotoxicity event following the administration of 5-FU or capecitabine (45).

However, there is still not enough evidence regarding the potential cardiotoxicity of both S1 and UTF, thus requiring particular attention and close monitoring when employed (46).

## Conclusion

Fluoropyrimidines (FP) cardiotoxicity is an elusive clinical condition and its recognition is challenging. At least half of the patients do not complain of angina or equivalents (and dizziness should be considered a warning symptom), and the ECG abnormalities may be absent at rest ECG.

Effort-induced clinical cardiotoxicity is characterized in about 50% of the cases by VA and by atypical symptoms (including dizziness). Thus, the patients undergoing FP therapy should be discouraged from affording any unusual physical effort.

ECG ischemic changes without angina, either detected at routine ECG, at Holter or evoked by a physical effort should be not disregarded as clinically irrelevant, as they may be a sign of even severe cardiotoxicity.

Active surveillance with ECG during CT and advising the patients to refer any new symptom may increase the detection of asymptomatic or oligosymptomatic cardiotoxicity. Also, a stress test, performed during active oncologic treatment, seems necessary to rule out the occurrence of cardiotoxicity events.

## Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## Ethics statement

This study was reviewed and approved by the Internal Review Board of the Centro di Riferimento Oncologico (CRO),

National Cancer Institute. Written informed consent was not required for this study in accordance with the local legislation and institutional requirements.

## Author contributions

CL: study planning, data collection and review, writing the draft, and the final manuscript. LC and LG: analysis of the clinical data and writing the manuscript. EV: data collecting, clinical evaluation, and follow-up of the patients. EB: data analysis. MC: revision of ECG tracing and editing of the manuscript. All authors contributed to the article and approved the submitted version.

## Funding

This study was financially supported by the Italian Ministry of Health-Ricerca Corrente to publishing this manuscript.

## Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

# Cardiovascular effects of immunosuppression agents

Aly Elezaby<sup>1,2</sup>, Ryan Dexheimer<sup>1</sup> and Karim Sallam<sup>1,2\*</sup>

<sup>1</sup>Stanford Cardiovascular Institute, Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Division of Cardiovascular Medicine, Department of Medicine, Stanford University, Stanford, CA, United States

Immunosuppressive medications are widely used to treat patients with neoplasms, autoimmune conditions and solid organ transplants. Key drug classes, namely calcineurin inhibitors, mammalian target of rapamycin (mTOR) inhibitors, and purine synthesis inhibitors, have direct effects on the structure and function of the heart and vascular system. In the heart, immunosuppressive agents modulate cardiac hypertrophy, mitochondrial function, and arrhythmia risk, while in vasculature, they influence vessel remodeling, circulating lipids, and blood pressure. The aim of this review is to present the preclinical and clinical literature examining the cardiovascular effects of immunosuppressive agents, with a specific focus on cyclosporine, tacrolimus, sirolimus, everolimus, mycophenolate, and azathioprine.

## KEYWORDS

immunosuppression, cardiovascular, hypertrophy, hypertension, mitochondria, fibrosis, toxicity

## Introduction

Medications that target and downregulate the immune system are utilized for the prevention and treatment of a variety of conditions, including neoplasms, autoimmune diseases, and acute rejection after solid organ transplantation (1). In a recent cohort, 2.8% of the adult population was treated with long-term immunosuppressive medications, consistent with prior self-reported estimates (2, 3). In addition to the well described increased risk of infection and malignancy in chronically immunosuppressed patients, many of these agents exhibit direct effects on the cardiovascular system including risk of left ventricular (LV) hypertrophy, myocardial fibrosis, arrhythmia, hypertension, dyslipidemia, and coronary atherosclerosis (4). Herein, we focus on the cardiovascular effects and mechanistic underpinnings of calcineurin inhibitors (CNI), mammalian target of rapamycin (mTOR) inhibitors, and purine synthesis inhibitors (Figure 1).

## Hypertrophy and fibrosis

Cardiac hypertrophy is a feature of adverse cardiac remodeling that may be driven by genetic or acquired factors. Hypertrophy is frequently seen in association with diastolic dysfunction and represents an important marker for adverse remodeling (5, 6). Much of the focus on immunosuppression-induced cardiac remodeling has been on the effects on cardiac hypertrophy in native or transplanted hearts (7–9) (Table 1).

## Calcineurin inhibitors

Calcineurin, a calcium and calmodulin-dependent phosphatase, plays a pivotal role in cardiac hypertrophy by translocating to the nucleus and dephosphorylating NFAT, allowing it to transcribe genes to activate hypertrophy in cardiomyocytes. Cyclosporine (CsA) binds to cyclophilin A, forming a complex with high affinity for calcineurin, which in turn inhibits its nuclear translocation. This is hypothesized to inhibit activation of NFAT-mediated hypertrophy (59). Tacrolimus binds to FK506-binding protein (FKBP12) to inhibit calcineurin activity driving reduced NFAT-mediated transcription of hypertrophic genes.

In early animal experiments, CsA successfully prevented or attenuated cardiac hypertrophy in mice overexpressing contractile elements (10, 29), genetic predispositions to hypertrophy (19), and treatment with exogenous chemical signals promoting hypertrophy (11, 15, 60). However, these data were challenged by the failure of CsA to prevent hypertrophy in several models of hypertension or pressure overload (16, 35, 61). Tacrolimus has also yielded mixed results. In murine models of genetic hypertrophic cardiomyopathy, tacrolimus exacerbated cardiac hypertrophy (37). In animal models of hypertrophy induced by phenylephrine stimulation, spontaneously hypertensive rats, or aortic banding, tacrolimus treatment had variable effects, with exacerbation or amelioration of the hypertrophic phenotype (16, 38, 61, 62).

Some hypothesized that the mixed results were driven by variability in hypertrophic signaling from genetic/sarcomeric-driven hypertrophic signaling vs. adaptive chemical or afterload-driven hypertrophy (37, 59). This hypothesis is somewhat weakened by mixed data for transverse aortic constriction rodent models.

Subsequent investigations suggested that CsA-induced effects on hypertrophic remodeling may be driven by increased fibrosis. Multiple studies have shown that CsA treatment led to increases in MMP2, MMP9, and Collagen I in dose dependent manner (20–22, 63). Rat hearts treated with CsA exhibited increased fibrosis/collagen content (64). Similar data of increased collagen deposition in response to tacrolimus treatment was observed in human induced pluripotent stem cell-derived cardiac organoids treated with tacrolimus (65). The *in*

*vitro* findings suggest that increased fibrosis is not a result of calcineurin-induced hypertension.

Notwithstanding some of the conflicting data in animal models, the data from humans have been fairly consistent as to the effects of CsA and tacrolimus on human hearts. Endomyocardial biopsies from heart or liver transplant patients treated with CsA showed structural distortion, increased fibrosis, and increased collagen levels (25, 26). Furthermore, patients treated with CsA and tacrolimus had hypertrophy or increased LV mass on autopsy or imaging (8, 26, 27, 39, 40). A clinical trial investigating the effect of CsA in patients with hypertrophic cardiomyopathy was initiated, but it is unclear if the study was completed and findings, if any, were not published (66).

Despite some earlier reports of amelioration of cardiac hypertrophy by CNI, there is no clear evidence in humans to corroborate this finding. Supported by *in vitro* and human data, a consistent signal of increased hypertrophy and fibrosis associated with CNI treatment is observed (23, 28). Cellular data highlight that the increase in LV mass may be driven primarily by CNI-induced increase in fibrosis and collagen deposition rather than cardiomyocyte remodeling.

## mTOR inhibitors

mTOR inhibitors, such as sirolimus and everolimus, inhibit mammalian target of rapamycin complex I, thereby inhibiting downstream pathways driving cell growth, proliferation, and survival. There are notable differences between sirolimus and everolimus (67). Everolimus is the 40-O-(2-hydroxyethyl) derivative of sirolimus, and differs in its subcellular distribution, pharmacokinetics and binding affinity. Compared to sirolimus, everolimus has higher bioavailability and shorter half-life. Both drugs form a complex with FKBP-12, which binds mTOR. However, everolimus binding to FKBP-12 is ~3-fold weaker than that of sirolimus, leading to significant differences in inhibition of mTORC2 activation and downstream effects (68, 69). Clinically this has translated into differences in side effect profile and potency of each drug.

This class of drugs has garnered significant interest in solid organ transplantation owing to salutary effects on renal function, allograft vasculopathy and malignancy risk (70). Sirolimus has been shown to reduce cardiac hypertrophy and fibrosis in animal models of pressure overload, uremia, and adriamycin induced cardiomyopathy (42, 43, 71). In a rat model of myocardial infarction, everolimus improved post-infarct remodeling (72) although in the recently published CLEVER-ACS trial of patients with myocardial infarction, there everolimus treatment had no effect on myocardial remodeling (73). Cellular data suggest that attenuation of adverse cardiac remodeling by mTOR inhibitors may be related

in part to reduced cardiac fibroblast proliferation and collagen secretion (65).

The favorable signal for sirolimus has been validated in human studies, which largely compared outcomes to subjects treated with CNI. Sirolimus has been associated with improvement in diastolic dysfunction and filling pressures, possibly through attenuation of fibrosis (47–49). In patients with heart transplantation, everolimus treatment was associated with less myocardial fibrosis than mycophenolate treatment by biopsy and imaging (50, 51). The data in kidney transplant patients has been more mixed with some suggesting less LV hypertrophy with the use of everolimus (74), while a number of randomized trials showed no difference in LV mass index after conversion from CsA to everolimus post-kidney transplant (52–55). The incidence of adverse cardiovascular events from these studies was mixed with the majority showing no differences in outcomes (75–77). This discordant signal may be related to the fact that kidney transplant recipients often have concomitant hypertension and activation of the renin-angiotensin system that may have already contributed to significant adverse cardiac remodeling prior to kidney transplant—making it less likely to observe differences following kidney transplantation (75, 78).

Additionally, most of the studies may have been underpowered to detect differences in cardiovascular outcomes.

## Purine synthesis inhibitors

Purine synthesis inhibitors block cell proliferation by preventing the synthesis of DNA and RNA during S phase of the cell-cycle. Mycophenolate mofetil (MMF) treatment has been shown to prevent or attenuate ischemic injury and autoimmune myocarditis in animal models, with reduced secretion of inflammatory markers such as TLR4, NFκB, BAX expression, and TNFα (57, 58). There are no human studies suggesting a link between cardiac hypertrophy or fibrosis in association with MMF or azathioprine use.

## Mitochondrial dysfunction

Mitochondria constitute a third of cardiomyocyte volume, and the heart, as a metabolically active organ, relies heavily on mitochondrial ATP production (79). Mitochondrial dysfunction

TABLE 1 Studies examining effects of immunosuppression on cardiac hypertrophy and fibrosis.

Agent	Species	Condition	Hypertrophy/Fibrosis	Studies
CsA	Rat, mouse	TAC	Attenuated LVH	(10–14)
	Mouse	TAC	No effect	(7, 15, 16)
	Rat	SHR	No effect	(16–18)
	Mouse	Gαq	Attenuated LVH	(19)
	Rat	Cardiac fibroblasts	No effect	(20)
	Rat	Cardiac fibroblasts	Induced fibrosis	(21–23)
	Rat	Langendorff	Decreased scar	(24)
	Human	Transplant	Increased LVH	(25–28)
	Human	LVH, HCM, CAD	Attenuated LVH	(29)
	Human	STEMI	Decreased scar	(30)
	Human	STEMI	No effect	(31–34)
Tacrolimus	Rat	SHR	Attenuated LVH	(35, 36)
	Mouse	Genetic HCM	Exacerbated LVH	(37)
	Rat	SHR, TAC	No effect	(16)
	Human	Transplant	Increased LVH	(26, 27, 38–40)
Sirolimus	Rat	Phenylephrine	Attenuated LVH	(41)
	Mouse, Rat	TAC	Attenuated LVH	(42, 43)
	Rat	Adriamycin	Attenuated fibrosis	(44)
	Mouse	Leprdb diabetic	Prevented fibrosis	(45)
	Rat	Zucker obese	Prevented fibrosis	(46)
		Zucker lean	Increased fibrosis	
	Human	Transplant	Regressed LVH	(47–49)
Everolimus	Human	Transplant	Attenuated LVH, fibrosis	(50, 51)
	Human	Transplant	No effect on LVH	(52–55)
	Rat	Metabolic syndrome	Attenuated LVH, fibrosis	(56)
MMF	Rat	Ischemia-reperfusion	Prevented apoptosis	(57)
	Rat	Myocarditis	Prevented LV dysfunction	(58)

is a feature of multiple types of cardiomyopathy, as it confers oxidative stress and changes in energetics to drive adverse cardiac remodeling. Immunosuppressive agents can exert direct effects on mitochondrial health to modulate cardiac remodeling and this has been subject of much investigation (Table 2).

## Calcineurin inhibitors

Cyclophilin D is a protein in the inner mitochondrial matrix involved in opening of the mitochondrial permeability transition pore (mPTP) (94). mPTP opening results in mitochondrial calcium overload, release of cytochrome C, a process involved in apoptosis and implicated in myocardial ischemia-reperfusion (IR) injury (80). CsA interacts with cyclophilin D thereby preventing mPTP opening and protecting the mitochondria from calcium overload. Tacrolimus does not bind cyclophilin D and the effects of tacrolimus on

mitochondrial function and mPTP opening are less defined. Multiple animal studies have sought to define the effect of both drugs on mitochondrial function.

CsA prevented mitochondrial-mediated injury and improved myocardial recovery in models of hypothermia, IR injury, and inborn errors of mitochondrial DNA polymerase (81–86, 95). In addition, CsA and/or tacrolimus have been associated with a favorable mitochondrial phenotype in the face of adriamycin treatment, hypoxia or endotoxemia (88–90).

Clinical data on the implications of these findings have been scant. In a single study of patients presenting with ST elevation myocardial infarction, CsA treatment decreased myocardial scar burden, which in combination with pre-clinical evidence provided promise for CsA as a “post-conditioning agent” during myocardial infarction (24, 30). However, follow-up studies failed to show any benefit to CsA treatment in regards to LV function, arrhythmia, or mortality (31–34). The discordance suggests that CsA protection from mitochondrial injury is largely a short term

TABLE 2 Studies examining effects of immunosuppression on cardiac mitochondrial function.

Agent	Species	Condition	Mito function	Studies
CsA	Rat	Isolated Mito	Protected from $\text{Ca}^{2+}$ overload, prevented mPTP opening	(80)
	Rat	Hypothermia	Improved ATP levels	(81)
	Rat	IR injury	Prevented mito injury	(82, 83)
	Mouse	Mito DNA mutations	Prevented mito injury	(84)
	Pig, Rat	Cardioplegic arrest	Prevented mito injury	(85, 86)
	Pig	HFpEF	Attenuated mito dysfunction	(87)
	Mouse	Adriamycin	Prevented loss of mito membrane potential	(88)
	Feline	Endotoxemia	Normalized mito respiration	(89)

TABLE 3 Studies examining effects of immunosuppression on arrhythmia.

Agent	Species	Condition	Arrhythmia	Studies
CsA	Rat	Injection	Sinus tachycardia, QT prolongation	(101)
	Rat	Oxidant stressor	Failed to suppress ventricular arrhythmia	(102)
	Rabbit	Atrial myocyte	Prevented cardiac alternans, decreased AF	(103)
	Canine	Pacing-induced AF	Prevented downregulation of LT $\text{Ca}^{2+}$ channel $\alpha$ -1c expression	(104)
	Canine	Chronic AV block	Prevented polymorphic ventricular tachycardia	(105)
	Mouse	Iron overload	Prevented arrhythmia	(106)
	Human	STEMI	No effect	(31–34)
	Human	Transplant	Case reports of increased arrhythmia	(107, 108)
Tacrolimus	Guinea pig	Injection	Dose-dependent QT prolongation	(109, 110)
	Pig, rat	Isolated myocytes	Increased $\text{Ca}^{2+}$ transients, prolonged action potential	(111–114)
	Rat	IR injury	Decreased ventricular arrhythmias	(115)
	Human	Transplant	Case reports of arrhythmias	(116–118)
Azathioprine	Human	Transplant	More atrial arrhythmias than MMF	(119)
	Human	Ulcerative colitis, psoriasis	Case reports of atrial fibrillation	(120–123)

STEMI, ST elevation myocardial infarction AF, Atrial fibrillation; IR, Ischemia-reperfusion; AV, atrioventricular.

or acute benefit. No human studies to date have evaluated the effect of CNI on mitochondrial structure and function in light of associated cardiac remodeling.

## mTOR inhibitors

Sirolimus has been associated with a reduction in respiration and cellular energetics in cardiomyocytes (92). This effect has been attributed to the observation that mTOR may activate AMP-activated protein kinase to regulate cellular bioenergetics (96). In a mouse model of cardiac IR injury, sirolimus inhibited apoptosis and

improved cardiac performance *via* interaction with the mitochondrial ATP-sensitive potassium channel (93) and appears to reduce ER stress and cytochrome C release (97). In brain, sirolimus enhances the distribution of CsA into mitochondria, accentuating its effects of decreasing mitochondrial metabolism, whereas everolimus appears to antagonize the effects of CsA in mitochondria to increase energy metabolism (67, 98). At therapeutically relevant concentrations, everolimus, but not sirolimus, distributes into brain mitochondria (99, 100). As cited above clinical studies have suggested a favorable effect for mTOR inhibitors on cardiac remodeling—but data examining mitochondrial function is lacking.

TABLE 4 Studies examining effects of immunosuppression on hypertension.

Agent	Species	Condition	Hypertension	Studies
CsA, Tacrolimus	Rat	Injection	Develop HTN prior to LVH	(101)
	Rat	Isolated arteries	Enhanced vasoconstriction, endothelin-1 receptor activation, decrease in eNOS	(127–129)
	Human	Transplant	Increase in HTN after transplant, more in CsA than tacrolimus	(130–132)
Sirolimus	Rat	Mineralocorticoid	Normalized systolic blood pressure	(133)
	Bovine	Endothelial cells	Restored eNOS-mediated vasodilation	(134)
	Human, mouse	PAH	Alleviated hypoxia-induced exacerbation of PAH	(135)
Everolimus	Human	Primary aldosteronism	Associated with improvement in blood pressure	(136)
	Human	Transplant	Lower incidence of HTN compared to CNI	(137)
	Human	PAH	Improvement in pulmonary vascular resistance	(138)
	Human	Renal cell carcinoma	Increased incidence of HTN when used in conjunction with Lenvatinib	(139)
MMF	Mouse	Systemic lupus erythematosus	Lowered blood pressure	(140, 141)
	Rat	Lead-induced HTN	Attenuated HTN	(142)
	Rat	Mineralocorticoid HTN	Prevented hypertension	(143, 144)
	Human	Psoriasis, rheumatoid arthritis	Lowered blood pressure	(145)
Azathioprine	Rat	Pregnancy-associated HTN	Attenuated hypertension	(146)
	Human, Rat	PAH	Improved pulmonary vascular resistance	(147)
	Human	Transplant	Less likely to develop hypertension than CsA group	(148)

HTN, Hypertension; PAH, pulmonary arterial hypertension; eNOS, endothelial nitric oxide synthase.

## Purine synthesis inhibitors

There are no reports of direct effects of MMF and Azathioprine on mitochondrial function in cardiomyocytes or heart tissue.

## Arrhythmia

With described effects on myocardial structural remodeling and intracellular ion transporter function, immunosuppressive therapies may modulate the risk of arrhythmia. This poses significant short- and long-term risks, especially in patients with underlying structural heart disease and heart transplant recipients (Table 3).

## Calcineurin inhibitors

Calcineurin affects intracellular calcium transients in cardiomyocytes *via* modulation of the ryanodine receptor and activation of the NFAT pathway, which drives transcriptional changes in proteins regulating intracellular calcium (124). Calcineurin inhibitors in turn can play a role in mediating changes in calcium transients impacting the electrical phenotype of the heart.

Delineating the precise effect of CNI on calcium regulation in human cardiomyocytes has proven elusive.

In some models CsA appeared to reduce sarcoplasmic reticulum (SR) calcium release and cytosolic levels of  $\text{Ca}^{2+}$  (106). However, other models showed that both CsA and tacrolimus result in increased  $\text{Ca}^{2+}$  release events and an increase in QT prolongation. A possible mechanism of QT prolongation may be an increase in the duration of  $\text{Ca}^{2+}$  transients due to blockade of  $\text{Na}^{2+}/\text{Ca}^{2+}$  exchanger. It is possible that CsA and tacrolimus exert different electrical phenotypes owing to their differential role in mitochondrial  $\text{Ca}^{2+}$  regulation and mPTP opening. Nonetheless the results in animal models of both drugs have been equally mixed; in some animal models, the cellular phenotypes of CNI appeared to translate to a reduced propensity to arrhythmia (103, 105, 106), but not in other models (101, 102).

Clinically, in case reports, CsA and tacrolimus induced atrial fibrillation and tacrolimus induced QT prolongation and atrial arrhythmias (107, 116). However, neither signal was seen in clinical trials with either drug suggesting that the arrhythmic risk is low (125, 126).

## mTOR inhibitors

There are no published reports of mTOR inhibitors modulating risk of arrhythmias. The recently published CLEVER-ACS trial showed no difference in atrial arrhythmias in patients treated with everolimus after myocardial infarction (73).

TABLE 5 Studies examining effects of immunosuppression on vascular remodeling.

Agent	Species	Condition	Vascular remodeling	Studies
CsA	Mouse	Endothelial and vascular smooth muscle cells	Increased endothelial cell activation, cytokines	(152)
	Rat	Isolated arteries	Increased endothelial dysfunction, oxidative stress, inflammation, smooth muscle proliferation	(128, 159–162)
	Human	Transplant	Associated with proliferative coronary vasculopathy	(163–165)
Tacrolimus	Human Rat	Norepinephrine Acetylcholine	Increased endothelial toxicity, impaired smooth muscle relaxation	(166)
	Human	Transplant	Less vasculopathy than CsA	(167–169)
Sirolimus	Rat	Mineralocorticoid, allografts, shear stress	Inhibited ROS, inflammation, intimal proliferation	(133, 170, 171)
	Pig Rat Human	Smooth muscle	Inhibited cell migration, proliferation	(172–174)
	Human	Transplant	Slowed coronary vasculopathy progression	(175, 176)
	Human	Transplant	Lowered PWV, arterial stiffness	(177, 178)
	Human	Coronary stenting	Prevented intimal proliferation	(179)
Everolimus	Rabbit	Carotid arteries	Improved vascular inflammation, thickening	(180)
	Mouse	LDL-receptor knockout	Prevented atherosclerosis	(181, 182)
	Human	PAH	Improved pulmonary vascular resistance	(138)
	Human	Transplant	Reduced CAV incidence/severity	(183, 184)
	Human	Transplant	No effect on pulse wave velocity	(75)
MMF	Rat	Lead-induced HTN	Decreased inflammation, intimal thickening	(142)
	Human	Transplant	Decrease in atherosclerosis, CAV	(119, 185, 186)
	Human	HUVEC + CNI	Prevented ROS production	(187)
AZA	Rat	Pregnancy-associated HTN	Attenuated endothelial cell dysfunction	(146)
	Rat	Subarachnoid hemorrhage	Attenuated vasospasm, reduced endothelin-1	(188)
	Mouse	Transgenic atherosclerosis	Inhibited atherosclerosis, decreased endothelial monocyte adhesion	(189)
	Human	HUVEC	Decreased cell proliferation	(190)

ROS, reactive oxygen species; PAH, pulmonary arterial hypertension; HUVEC, human umbilical vein endothelial cells; AZA, azathioprine; PWV, pulse wave velocity.

## Purine synthesis inhibitors

Azathioprine use is associated with increased incidence of atrial arrhythmias. In a 3-year randomized controlled trial of azathioprine vs. MMF, heart transplant patients treated with azathioprine had a higher rate of atrial arrhythmias than those on MMF (119). The mechanism for this phenomenon is unknown. There are no published reports of MMF modulating arrhythmia risk.

## Hypertension

Hypertension is a well described side effect of immunosuppressive medication use, particularly CNI, and

is associated with increased risk of coronary artery disease, cerebrovascular events, renal dysfunction, and adverse cardiovascular remodeling (Table 4).

## Calcineurin inhibitors

CNI are known to cause hypertension, with 50–80% of patients reported to have hypertension with chronic use. CsA is associated with a higher incidence compared to tacrolimus (130). CNI are implicated in afferent arteriole vasoconstriction and activation of the renin-angiotensin system, promoting sodium retention and volume expansion (127, 149). Furthermore, CsA and tacrolimus are associated with promoting direct vasoconstriction by one or more of the following

TABLE 6 Studies examining effects of immunosuppression on dyslipidemia.

Agent	Species	Condition	Dyslipidemia	Studies
CsA	Human	Transplant	Increased total cholesterol, LDL, decreased HDL	(202, 203)
	Human	Transplant	Increased cholesteryl ester transfer protein, lipoprotein lipase activity, decreased lipolysis	(204, 205)
	Human	Transplant	Pro-oxidant effect on LDL	(206, 207)
Tacrolimus	Mouse	High vs low dose	High dose developed hypercholesterolemia, low dose did not	(208)
	Human	Transplant	Less significant increase in LDL, total cholesterol than CsA	(130, 209–213)
	Human	Transplant	Less pro-oxidant effect on LDL than CsA	(206, 207)
	Human Mouse	HUVEC, diabetic mice	Decreases oxidized LDL uptake to endothelial cells, smooth muscle cells	(214–216)
	Mouse	Pcsk9 knockout	Increased PCSK9 expression, leading to decreased LDL receptor expression, increased LDL	(217)
	Human	Transplant	Increase in cholesterol, triglycerides	(70, 218)
	Human	Transplant	Increased apolipoprotein C-III, lipoprotein lipase	(204, 219)
Everolimus	Mouse	LDL-receptor knockout	Increased VLDL/LDL, inhibited atherosclerosis	(181, 182)
	Human	Transplant	No additive increase in total cholesterol and triglycerides	(220)
	Human	Transplant	Similar dyslipidemia to sirolimus	(221)
	Human	Transplant	Decreased oxidized LDL	(222)
	Human	Transplant	No change in lipids, increase in PCSK9	(223, 224)
MMF	Rabbit	High-cholesterol diet	No effect on LDL, HDL, or triglyceride levels	(225)
	Human	Transplant	Cholesteryl ester transfer protein activity unchanged with MMF	(131, 204, 226)
Azathioprine	Human	Transplant	Conversion from CsA decreased total cholesterol, LDL, triglycerides, improved LDL oxidation	(227)
	Human	Transplant	Did not alter serum lipids in comparison to MMF	(228)

mechanisms: increased tone of vascular smooth muscle (128, 150, 151), reduced nitric oxide production (129), and activation of endothelin-1 receptor (129). In cultured murine endothelial and vascular smooth muscle cells, both CsA and tacrolimus were associated with production of proinflammatory cytokines and endothelial activation, with increased superoxide production and NF- $\kappa$ B regulated synthesis of proinflammatory factors, which were prevented by pharmacological inhibition of TLR4. This raises the possibility that a proinflammatory milieu drives chronic endothelial dysfunction, contributing to CNI-induced hypertension (152).

There is some controversy as to whether the clinical hypertrophic phenotype is related to direct myocardial effects or is in fact due an increase in the incidence of hypertension associated with CsA use. Observations that rats treated with CsA develop hypertension prior to myocardial hypertrophy (4, 101, 153–155) supported the notion that perhaps the clinical hypertrophic phenotype is purely related to CNI-induced hypertension rather than direct myocardial effects. While hypertension may be a contributor to the

hypertrophic phenotype observed, multiple animal and cellular models have supported a direct effect of CNI on myocardial remodeling.

## mTOR inhibitors

mTOR inhibitors have been associated with a lower risk of hypertension compared to calcineurin inhibitors when used in solid organ transplant recipients (137, 156). The difference between effects of CNI and mTOR inhibitors is likely driven by multiple mechanisms with an overall vasodilatory effect of mTOR inhibitors (157, 158). Sirolimus and everolimus appear to increase nitric oxide production preventing endothelial hyperplasia and dysfunction (133, 134). This promising anti-hypertensive profile has led to the consideration of mTOR inhibitors as a primary therapy for specialized difficult-to-treat populations with hypertension including pulmonary arterial hypertension and primary hyperaldosteronism (138, 139).

## Purine synthesis inhibitors

Purine synthesis inhibitors are not associated with hypertension and may in fact have an antihypertensive effect. In comparison to patients treated with CsA after heart transplantation, those treated with azathioprine were less likely to develop hypertension (148). Lower blood pressures have been reported in patients taking MMF for psoriasis and rheumatoid arthritis (145). Possible mechanisms for the favorable hypertensive profile include: lower pro-inflammatory signaling that drives endothelial dysfunction and hyperplasia, decreased circulating levels of endothelin-1, and reduced sodium reabsorption and neuro-hormonal activation leading to hypertension (142–144). Taken together, these data suggest that purine synthesis inhibitors carry a lower risk of systemic hypertension, and may in fact contribute to favorable mechanisms to reduce hypertension in pulmonary hypertension and renal dysfunction-associated hypertension.

## Vascular remodeling

In addition to effects on hypertension, immunosuppressive agents may directly contribute to abnormal vascular remodeling to drive cardiovascular adverse events, independent of hypertension or dyslipidemia. Defining this risk and the contributing mechanisms for each drug is important in order to ensure appropriate follow up and identify potential actionable targets to modify the risk profile (Table 5).

## Calcineurin inhibitors

CNI, particularly tacrolimus, have been associated with increased risk of allograft vasculopathy (167–169, 191). This notable complication of transplanted hearts represents a major driver of graft dysfunction and has significant implications for quality of life and longevity of heart transplant recipients (163–165). This has been replicated in animal models using both tacrolimus and CsA with adverse remodeling features of vascular stiffness, thickening, inflammation and fibrosis noted in treated animals (159, 160). The mechanisms for these include: decreased fibrinolytic activity in vessel walls, increased oxidative stress in endothelial cells, and possibly increased intracellular calcium in vascular smooth muscle cells (161, 162, 192).

## mTOR inhibitors

Both sirolimus and everolimus have been associated with a more favorable vascular profile and their clinical efficacy in reducing the rate of progression of cardiac allograft vasculopathy has led to widespread use in heart transplant recipients

(175, 176, 183). In addition to reducing signaling associated with endothelial dysfunction, mTOR inhibitors have been shown to reduce vascular smooth muscle proliferation, intimal hyperplasia, and infiltration by inflammatory cells (170–173, 193, 194). Everolimus, in particular, was shown to reduce pro-inflammatory signaling by decreasing IL-9, VEGF release, and TNF $\alpha$  induced adhesion of endothelial cells (184). These effects have led to wide adoption of everolimus- and sirolimus-eluting stents in the treatment of coronary artery disease (179, 195, 196).

In several trials of kidney transplant patients, a switch from CsA to mTOR inhibitor was associated with stabilization or improvement in parameters of arterial stiffness, including pulse wave velocity (PWV), carotid systolic blood pressure, pulse pressure, and augmentation index (177, 178). One notable exception was a secondary analysis of the ELEVATE trial, where no difference in PWV was found with switch from CsA to everolimus, which was attributed to significant variation in baseline PWV in the study population (75).

In addition to reducing allograft vasculopathy, the anti-vascular proliferation signal conferred by mTOR inhibitors has made the drug class of substantial interest in oncology to suppress tumor neovascularization. Nonetheless, while this anti-proliferation profile offers a substantial benefit, it carries some drawbacks; Namely, both mTOR inhibitor drugs are associated with an increased incidence of lymphedema, which is thought to be driven by inhibition of lymphatic endothelial cell proliferation (197, 198). The incidence of such side effects must be considered in oncologic therapy, where drug dosage is typically higher than that used in transplant immunosuppression (199).

## Purine synthesis inhibitors

Purine synthesis inhibitors appear to confer a beneficial vascular remodeling profile. MMF has been associated with reduced atherosclerosis progression and CAV in patients and animal models (119, 142, 185). Animal models point to a signal of decreased vascular oxidative stress and inflammation as the driving mechanism of that benefit (187, 200, 201). Reduced endothelial and smooth muscle proliferation in association with MMF have also been proposed as a possible mechanism, although the evidence is more limited than for mTOR inhibitors (190).

## Dyslipidemia

Immunosuppressive medications are associated with dyslipidemia. Each drug class is associated with individual variations in affected lipid particles and more importantly in the conferred risk of atherosclerosis (Table 6).

## Calcineurin inhibitors

CsA use is associated with a dose-dependent increase in total cholesterol and low-density lipoprotein (LDL) cholesterol, a decrease in high-density lipoprotein (HDL) cholesterol, and an increase in serum triglycerides (202, 203). These changes are driven by a decrease in lipoprotein lipase and an increase in activity of cholesteryl ester transfer protein (204, 229). Additionally, CsA may reduce expression of the LDL receptor, thereby impairing LDL clearance (230–232). Tacrolimus is associated with a similar, but milder, dyslipidemia profile compared to CsA (130, 209–212). CsA appears to be associated with an increase in oxidized LDL, which confers a higher risk of atherosclerosis, while the data for tacrolimus effect on LDL oxidation are mixed (206–208).

## mTOR inhibitors

Sirolimus is a stronger inducer of hyperlipidemia than CNI, associated clinically with an increase in serum LDL and triglyceride levels (70, 218, 233). The mechanism remains unclear, although it may be due to a combination of reduced catabolism, an increase in the free fatty acid pool, increased hepatic production of triglycerides, and secretion of very low density lipoprotein (VLDL) (204, 217). In addition, sirolimus is associated with an increase in serum PCSK9 levels, which acts as a post-transcriptional regulator of LDL receptor expression (234). Clinical data on the risk of dyslipidemia associated with everolimus has been mixed. In clinical studies, everolimus was not associated with an increased risk of dyslipidemia compared to CNI (220, 222, 223, 235–237). However, a meta-analysis comparing mTOR inhibitors to CNI adverse events has noted no difference between sirolimus and everolimus in the incidence of dyslipidemia (238). This suggests that everolimus may contribute to dyslipidemia, but at an intensity that is between CNI and sirolimus.

Interestingly, despite the increase in serum lipids, mTOR inhibitors are associated with an overall lower risk of atherosclerosis (195). Sirolimus reduces oxidized-LDL adhesion and uptake to endothelial cells, and can promote its autophagic degradation (214, 215). Additionally, sirolimus reduces intracellular lipid accumulation in vascular smooth muscle cells, and increases cholesterol efflux *via* increased expression of the ATP binding cassette protein ABCA1 (216). Similarly everolimus treatment in LDL receptor knockout mice, everolimus increased VLDL/LDL levels but reduced the rate of atherosclerosis. Thus, regardless of dyslipidemia profile, mTOR inhibitors appear to result in a net reduction in the rate of atherosclerosis, which may explain the overall clinical benefit observed.

## Purine synthesis inhibitors

Both MMF and azathioprine appear to have a neutral effect on lipids with no significant changes observed in lipid profile in clinical studies (131, 226–228). *In vitro* studies suggest that MMF increases cholesterol efflux, but another study demonstrated inhibition of lipoprotein lipase activity—the opposing effects may explain the net neutral profile conferred by the drug.

## Drug exposure and bioavailability

It is important to note that the bioavailability and exposure levels of the immunosuppression drugs have varied tremendously across clinic and scientific studies in the field. This may explain the differences observed between pre-clinical and clinical studies or even discrepancies between different clinical studies. Part of this variation is not simply investigator mediated, but is driven by variability in clinical practice by geographic area and changes in clinical practice over time. Early CsA trough concentrations in kidney transplant patients ranged 200–500 µg/ml, whereas in Europe, they were typically lower (100–200 µg/ml). Similarly, tacrolimus trough levels ranged 12–20 ng/ml in the US, and lower in Europe (8–15 ng/ml). There were also variations in sirolimus and everolimus levels when used in combination with CNI. MMF was previously prescribed at higher doses than is typically used now (2–3 g twice daily to 1 g twice daily) (12, 55, 107, 131).

## Conclusions

Immunosuppressive agents exert significant effects on the heart and vasculature. Mechanistic studies point toward immunosuppression drug-specific influences on changes in cell proliferation, mitochondrial function, inflammatory cytokines, and altered calcium handling as potential mediators of these phenotypes. Calcineurin inhibitors promote cardiac hypertrophy, hypertension, dyslipidemia, and vascular remodeling, while mTOR inhibitors have an anti-proliferative effect with attenuation of cardiac hypertrophy and vascular remodeling despite promoting dyslipidemia. Purine synthesis inhibitor are less well studied, but may have a neutral to mildly positive effect on hypertension and vascular remodeling. These phenotypes are associated with significant morbidity in patients taking immunosuppressive medications, carrying increased risks of heart failure, cardiovascular disease, and kidney dysfunction. While preclinical studies have provided invaluable insight into mechanisms of cardiovascular remodeling, the discordance with clinical data, such as in the case of CNI and hypertrophy, highlights the importance of caution in generalizing the results of cell-based and animal models. Further translational research is needed to identify actionable

targets to treat associated cardiovascular side effects of immunosuppression drugs.

## Data availability statement

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

## Author contributions

AE, RD, and KS contributed to the writing and figures presented in the manuscript. All authors contributed to the article and approved the submitted version.

## Funding

NIH T32 HL09427411A1 (AE), NIH K08 HL135343 (KS), and American Heart Association and Enduring Hearts Grant # 924127/Sallam and Hollander/2022 (KS).

<sup>1</sup>The Second Xiangya Hospital, Central South University, Changsha, China, <sup>2</sup>National Clinical Research Center for Geriatric Disorders, Department of Geriatrics, Xiangya Hospital, Central South University, Changsha, China, <sup>3</sup>Department of Cardiovascular Medicine, The Second Xiangya Hospital, Central South University, Changsha, China

**Aim:** To explore the association of cardiac parameters with different clinical outcomes in patients with anti-PD-1 immunotherapy-induced myocardial injury.

**Methods and results:** We screened 3,848 patients who received anti-PD-1 immunotherapy from June 2018 to Oct 2021 at the Second Xiangya Hospital of Central South University. Among those patients, 134 patients were diagnosed with anti-PD-1 immunotherapy-induced myocardial injury. Twenty-four patients with cardiovascular symptoms were divided into the major adverse cardiac events (MACE) group, and 110 patients without cardiovascular symptoms were divided into the non-MACE group. We compared creatine kinase isozyme (CK-MB), high-sensitivity troponin T (hsTNT), N-terminal pro-B-type natriuretic peptide (NT-ProBNP), electrocardiography (ECG), and echocardiographic parameters between the two groups of patients. CK-MB, hsTNT, NT-proBNP [2,600.0 (1,317.00–7,950.00) vs. 472.9 (280.40–788.80),  $p \leq 0.001$ ], left ventricular end-diastolic diameter (LVEDd), left ventricular ejection fraction (LVEF) and QRS interval were significantly different. The receiver operating characteristic (ROC) curve was used to compare the accuracy of various indicators to predict the occurrence of MACE events. NT-ProBNP (area under the curve [AUC] 97.1) was the best predictor, followed by CK-MB (AUC = 94.1), LVEF (AUC = 83.4), LVEDd (AUC = 81.5), and other indicators. In the MACE group, 11/24 patients had experienced cardiogenic death by the end of follow-up. There were significant differences in the CK-MB, hsTNT, NT-proBNP, LVEDd, LVEF, and QRS intervals between the deceased patients and the survivors. The ROC curve shows that hsTNT is the most accurate marker for predicting cardiogenic death in the MACE group (AUC = 91.6).

**Conclusion:** In patients with myocardial injury after PD-1 inhibitor treatment, NT-proBNP is the parameter of choice to predict the likelihood of developing cardiovascular symptoms, whereas, in symptomatic patients, hsTNT is the

optimal parameter associated with the outcome of death compared with other cardiac parameters.

cardiac parameters, anti-PD-1 immunotherapy, myocardial injury, prognostic predictor, cardiogenic death

## Introduction

Cancer and cardiovascular diseases are the two most important categories of diseases affecting human health (1). Immunotherapy has advanced rapidly in the treatment of tumors in recent decades (2). In particular, immune checkpoint inhibitors (ICIs) represented by anti-programmed cell death-1 (PD-1) antibody therapy are one of the most commonly used immunotherapy methods worldwide (3). According to the guidelines published by multiple oncology organizations around the world (4, 5), PD-1 inhibitors have become a standard treatment for a variety of solid advanced malignancies, and immunotherapy-induced myocardial injury has increasingly been recognized with the widespread use of these agents (6). Some patients have only isolated elevation of serum markers of myocardial injury without any complaints, such as creatine kinase isozyme (CK-MB), high-sensitivity troponin T (hsTnT), and N-terminal pro-B-type natriuretic peptide (NT-proBNP). However, some patients treated with anti-PD-1 inhibitors also have severe cardiovascular manifestations, such as heart failure (HF), malignant arrhythmias, and death, even though a lower incidence of 0.3–2% has been reported in the literature (7, 8). The mechanism leading to this completely different clinical outcome is not yet been fully understood and may be related to the excessive activation of inflammation. In addition, whether patients with asymptomatic myocardial injury need treatment is unclear. Regardless, it is foreseeable that the use of ICIs will continue to increase as the cost decreases, and therefore, how to accurately identify the severity of PD-1 inhibitor-induced myocardial injury at an early stage is of great importance but remains unclear.

Our objective was to identify the association of cardiac parameters with different clinical outcomes in patients with anti-PD-1 immunotherapy-induced myocardial injury and find a better cardiac parameter to predict these outcomes of different severities.

## Patients and methods

### Patients

This is a retrospective cohort study, we screened 3,848 patients who received anti-PD-1 immunotherapy from

June 2018 to Oct 2021 at the Second Xiangya Hospital of Central South University. Among those patients, 134 patients were diagnosed with anti-PD-1 immunotherapy-induced myocardial injury. These patients were from the Department of Oncology, Department of Respiratory Medicine, Department of Cardiology, Department of Thoracic Surgery, Department of Critical Medicine, and Department of Emergency. Medical records are from the inpatient, outpatient, and emergency medical systems. Data including demographic characteristics, comorbidities, main complaint at diagnosis, laboratory testing results, electrocardiography (ECG), echocardiographic findings, and treatment were obtained. The study protocol conformed to the ethical guidelines of the Declaration of Helsinki (9) as reflected by prior approval from the human research committee of the Second Xiangya Hospital of Central South University. Written informed consent was obtained from patients while the patient was in a clinically stable, non-congested condition or from their family members who could give informed consent on behalf of patients after they were informed about the objectives and procedures of the study. Their rights to refuse participation any time they wanted were assured. For this purpose, a one-page consent letter was attached as a cover page of each questionnaire stating the general objective of the study and issues of confidentiality that were discussed by the data collectors before proceeding with the data collection.

### Diagnostic procedures

A total of 3,848 patients who received PD-1 antibody therapy were evaluated. The inclusion criteria were as follows: (1) High-sensitivity troponin T was negative in patients before PD-1 antibody treatment, but the concentration increased in patients after treatment. The exclusion criteria were: (1) Acute or suspected renal function injury leading to false elevation of high-sensitivity troponin T levels; and (2) Use of other drugs that may cause myocardial injuries, such as anthracycline chemotherapeutic drugs, cyclophosphamide, and trastuzumab. Finally, 134 patients were included in the study (see flowchart in Figure 1 for details).

## Data collection

Demographic and clinical characteristics were collected when the diagnosis of PD-1 inhibitor-induced myocardial injury was confirmed. Blood test parameters, ECG, and cardiac ultrasound parameters were the first reports obtained after diagnosis. Patient-reported comorbidities were listed according to what the patient told our doctor on admission and what we diagnosed after discharge. The tracking of hsTnT and NT-proBNP is generally divided into two situations. The first is that it is detected in our hospital when symptoms appear. The second is the routine detection of asymptomatic patients on admission for anti-tumor treatment. High-sensitivity troponin T (hsTnT) was measured by electrochemiluminescence (Roche, Germany). The upper limit of the reference value (99th quantile) in the manual is 14 pg/ml.

## Definitions and outcome

The outcome of interest, major adverse cardiac events (MACE), was a composite of cardiovascular death, cardiac arrest, HF, and arrhythmias that cause hemodynamic abnormalities such as tachyarrhythmias/bradyarrhythmias

and acute myocardial infarction (AMI). For cases where cardiac arrest, HF, arrhythmias, and AMI led to death, the outcome was counted as cardiac death. Standard definitions were used for cardiovascular death, cardiac arrest, HF, and AMI (10, 11). Survival time (days) was measured as the duration between the first day of hospitalization when the patient received PD-1 antibody therapy to the date of MACE or death from any cause. Data were obtained from medical records or from telephone interviews with patients or relatives by 2 trained physicians. We chose to set the follow-up time to 90 days because previous clinical studies showed that the vast majority of cardiotoxicity occurred within 90 days following the use of PD-1 inhibitors (12). Patients were followed until 16 October 2021. Patients were censored if they were still alive at the end of the research period or were lost to follow-up, on which occasion their last clinic visit or correspondence time was used.

## Statistical analysis

Normally distributed parameters are expressed as the mean  $\pm$  standard deviation (SD), whereas non-normally distributed parameters are expressed as the median with interquartile range (IQR). Categorical values are presented as numbers

(percentages). Categorical data were reported as frequencies and percentages and were compared using the chi-squared or Fisher's exact test. Comparison of continuous variables between two independent groups was performed using an unpaired Student's *t*-test (if normally distributed) or the Mann–Whitney *U* test (non-normally distributed variables), and in cases where more than two groups were compared, one-way analysis of variance (ANOVA) or the Kruskal–Wallis test was used. Univariate analyses were performed to examine the correlates between cardiac parameters and different outcomes using the logistic regression models. The receiver operating characteristic (ROC) curve was used to reflect the accuracy of different cardiac parameters in predicting different outcomes by the area under the curve (AUC). Survival was evaluated with Kaplan–Meier curves. All tests were two-tailed and a *p*-value of  $< 0.05$  was considered to indicate statistically significant. Statistical analysis was performed using SPSS 26.0 (IBM Software Inc), EmpowerStats 3.0 software, and R (version 3.3.2).

## Results

### Patient characteristics

In the MACE group, 16 patients had a new onset HF, 3 patients had non-ST segment elevation myocardial infarction (NSTEMI), 3 patients had new-onset symptomatic arrhythmia, and 1 patient had a sudden cardiac arrest. In the non-MACE group ( $n = 110$ ), no patients presented with clinical symptoms of the cardiovascular system. Although high-sensitivity troponin T or NT-proBNP levels were significantly higher than before PD-1 antibody administration. The MACE group was older than the non-MACE group ( $66.5 \pm 8.1$  vs.  $60.4 \pm 9.9$   $p = 0.01$ ). In addition, the MACE group had more concurrent side effects, such as PD-1-mediated pneumonia [7/24 (29.2%) vs. 1/110 (0.9%)], hepatitis [3/24 (12.5%) vs. 3/110 (2.7%)], myositis [4/24 (16.7%) vs. 3/110 (2.7%)], and thyroid dysfunction [5/24 (20.8%) vs. 16/110 (14.5%)]. Regarding sex, 75% (18/24) of patients in the MACE group were male, and 78.2% (86/110) in the non-MACE group were male. There was no significant difference in the gender distribution between the two groups (Table 1).

### Cancer characteristics of interest

The time from the first day of PD-1 inhibitor treatment to the date when PD-1 inhibitor-induced myocardial injury diagnosis was confirmed was  $37.04 \pm 20.26$  days for the MACE group and  $32.85 \pm 17.97$  days for the non-MACE group. Regarding the tumor proportion scores (TPS) of PD-1 expression by tumor tissue immunohistochemistry, there was no difference between the two groups ( $47.35 \pm 27.51$  vs.  $44.12 \pm 27.23$ ,  $p = 0.654$ ). Regarding the anti-tumor regimen,

7 (29.2%) patients in the MACE group and 40 (36.4%) patients in the non-MACE group received PD-1 inhibitor monotherapy. The remaining cases were treated with chemotherapy combined with immunotherapy. More than half of the patients' primary tumors were non-small-cell lung cancer (NSCLC), followed by esophageal cancer, liver cancer, and other tumors (details in Table 1).

### Cardiac parameters among subjects

In the MACE group, CK-MB ( $108.97 \pm 57.09$  vs.  $31.86 \pm 43.66$ ,  $p \leq 0.001$ ), hsTNT [ $195.5$  (108.75–302.50) vs.  $78.00$  (47.85–124.00),  $p \leq 0.001$ ], and NT-proBNP [ $2,600.0$  (1,317.00–7,950.00) vs.  $472.9$  (280.40–788.80),  $p \leq 0.001$ ] levels were significantly higher than those in the non-MACE group. Regarding the parameters of echocardiography, in the MACE group, patients had a higher left ventricular end-diastolic diameter (LVEDd) ( $51.5 \pm 6.1$  vs.  $43.5 \pm 6.2$ ,  $p \leq 0.001$ ) and lower left ventricular ejection fraction (LVEF) ( $46.7 \pm 9.1$  vs.  $57.2 \pm 7.5$ ,  $p \leq 0.001$ ) than those in the non-MACE group. There were no significant differences in other cardiac parameters between the two groups (Table 2). The ECG parameters between the two groups were also somewhat different. The incidence of bradyarrhythmia and tachyarrhythmia in the MACE group was higher than that in the non-MACE. The QRS interval of the MACE group was significantly wider than that of the non-MACE group ( $127.2 \pm 33.5$  vs.  $93.7 \pm 16.1$ ,  $p = 0.001$ ), but the corrected QT interval of the two groups was no different (details in Table 2).

### Outcome of all cases

The median follow-up of all cases was 90 days (12–102 days). In the MACE group, 13/24 of patients survived after careful treatment. The number of all-cause deaths in the MACE group was 12 (50%) as of the end of follow-up, and one of them was non-cardiogenic death (lung infection). For the non-MACE group, 16/110 (14.5%) of patients had non-cardiogenic deaths, and the rest were still alive at the end of follow-up. The K–M survival curves of the two groups are shown in Figure 2.

### Cardiac parameters among survivors and deceased patients in the MACE group

In the MACE group, 13/24 of patients survived after treatment, and 11/24 died after treatment. Compared with those of the survivors, the CK-MB ( $146.4 \pm 56.2$  vs.  $77.3 \pm 35.3$ ,  $p \leq 0.001$ ), hsTNT [ $300.0$  (218.5–729.0) vs.  $112.0$  (84.0–122.0),  $p \leq 0.001$ ], and NT-proBNP [ $8,400.0$  (3,850.0–14,000.0) vs.  $1,890.0$  (1,200.0–2,400.0),  $p \leq 0.001$ ] levels of the deceased

## The association between cardiac parameters and different outcomes

Univariate logistic regression was used to analyze the association between cardiac parameters and different outcomes. Age (*OR* = 1.08, 95% *CI* = 1.02–1.14, *p* = 0.007), CK-MB (*OR* = 1.03, 95% *CI* = 1.01–1.04, *p* < 0.001), hsTNT (*OR* = 1.01, 95% *CI* = 1–1.01, *p* = 0.001), NT-proBNP (*OR* = 1.0, 95% *CI* = 1.0–1, *p* < 0.001), LVEDd (*OR* = 1.21, 95% *CI* = 1.12–1.32, *p* < 0.001), LVEF (*OR* = 0.87, 95% *CI* = 0.82–0.93, *p* < 0.001), and QRS interval (*OR* = 1.04, 95% *CI* = 1.02–1.06, *p* < 0.001) were predictive of the development of cardiovascular symptoms (MACE events) in patients with PD-1 inhibitor-induced myocardial injury. The ROC curve was used to compare the accuracy of various indicators to predict the occurrence of MACE events. NT-ProBNP (*AUC* = 97.1) was the best predictor, followed by CK-MB (*AUC* = 94.1), LVEF (*AUC* = 83.4), LVEDd (*AUC* = 81.5), and other indicators, as

shown in **Figure 3A**. In the MACE group, CK-MB (*OR* = 1.04, 95% *CI* = 1.01–1.07, *p* < 0.021), NT-proBNP (*OR* = 1.0, 95% *CI* = 1–1, *p* < 0.042), hsTNT (*OR* = 1.02, 95% *CI* = 1–1.04, *p* < 0.034), and QRS duration (*OR* = 1.04, 95% *CI* = 1–1.07, *p* < 0.032) were predictors of death. The ROC curve revealed that hsTNT was the most accurate predictive marker (*AUC* = 91.6; more details in **Table 4** and **Figure 3B**).

## Discussion

This is a retrospective case analysis from a large referral hospital. We are deeply concerned about the increase in high-sensitivity troponin T levels after PD-1 inhibitor treatment, and previous studies have reported that the incidence is very low. In the safety study of more than 2,000 patients with immunotherapy released by Bristol-Myers Squibb, the rate of myocarditis in patients treated with ipilimumab or nivolumab

was 0.09%. Among patients receiving combination therapy, the incidence of myocarditis is approximately 0.3%, and its severity is greater than that of patients receiving monotherapy (8). A retrospective case study of PD-1 inhibitor treatment reported that the prevalence of myocarditis was 1.14% with a median time of onset of 34 days after starting PD-1 inhibitor treatment (*IQR*: 21–75 days) (13). Since many patients do not routinely have ECG and markers of myocardial injury monitored, some studies suggest or believe that the proportion of myocarditis caused by PD-1 inhibitors may be higher than 1% (7). However, in clinical practice, we often encounter patients who show only elevated levels of cardiac troponin, a marker of myocardial injury but have no symptoms after treatment with PD-1 inhibitors. These patients have not been well evaluated. Our study showed that 3.48% (134/3848) of patients had increased high-sensitivity troponin T levels after PD-1 inhibitor

monotherapy. This ratio is very high and still underestimated because some patients without cardiovascular symptoms have not been monitored for troponin levels. Our study indicated that 24 patients (0.62%) had cardiovascular symptoms, and 11 of them suffered cardiogenic death. If these symptomatic patients are defined as having myocarditis, this is equivalent to the incidence rate of previous studies.

Our study supports the need for routine monitoring of cardiac parameters in patients using PD-1 inhibitors. Oncologists in many countries currently recommend routine detection of myocardial injury markers, such as CK-MB, CK, troponin, and BNT-proBNP, during each cycle of PD-1 inhibitors (14, 15). However, the importance of the elevated levels of each marker is unclear, and cardiovascular physicians often go to the oncology department for consultation. Our study indicates that the higher the increase in these cardiac

markers levels, the greater the probability of occurrence of cardiac symptoms. In addition, our study indicates that the QRS interval on ECG is also a clinical indicator for predicting whether patients will have symptoms, which suggests that ECG is also very important in monitoring patients for adverse drug reactions. This is similar to a previous study by Zlotoff et al., which showed that the QRS duration is increased in ICI myocarditis and is associated with increased MACE risk, especially in patients whose QRS interval is greater than 110 ms (16). We think this is mainly related to the occurrence of more ventricular arrhythmias in the MACE group. With an increasing number of ventricular arrhythmias, the probability of cardiovascular symptoms will obviously increase. Of course, cardiac ultrasound is a very accurate tool to judge whether a patient has cardiac dysfunction, especially the LVEF is a very important indicator. However, using the ROC curve

for comparison, NT-proBNP is the best cardiac parameter predicting clinical symptoms in patients with PD-1 inhibitor-mediated myocardial injury. This may be related to the fact that most patients in the MACE group present with symptoms of HF.

Our study indicated that the most common occurrence of cardiovascular system symptoms after PD-1 inhibitor treatment is HF symptoms, manifested as dyspnea and edema. Then, five patients presented with chest pain, four patients experienced palpitations, and one patient died suddenly after elevated troponin levels were observed. Notably, 62.5% (16/24) of patients in the MACE group entered the intensive care unit for treatment. However, 45.8% (11/24) of the patients eventually experienced cardiogenic death. Such a high mortality rate is similar to that reported in Western countries (17–19). Additionally, the proportion of corticosteroid treatment was

QRS duration	1.04 (1~1.07)	<b>0.032</b>

relatively low compared to that in Western countries; 23 patients in the MACE group received treatment, and 13 patients received glucocorticoids. A recent study (20) showed that the dose of corticosteroids is negatively correlated with the mortality of patients with PD-1 inhibitor-mediated myocarditis. However, these results increase the possibility that myocardial injury can be mitigated by early and intensive corticosteroid therapy. Nevertheless, the decision of whether to administer high-dose corticosteroids during clinical practice still requires consideration of various other aspects, especially infection. Certainly, we cannot rule out that this mortality rate is related to the conservative use of corticosteroid therapy. Despite the high mortality rate, we still need to risk stratify patients. We also used a logistic model to evaluate the relationship between various cardiac parameters and cardiogenic death. CK-MB, hsTNT, NT-proBNP, and QRS duration were statistically significant in predicting cardiogenic death in the MACE group. Using ROC curves for mutual comparison, hsTNT was the best marker for predicting cardiogenic death in the MACE group patients.

In 2018, the American Society for Clinical Oncology (ASCO) issued the clinical practice guidelines (21, 22) for cardiotoxicity related to ICIs. Based on this guideline, cardiotoxicity is divided into four levels according to severity (23). Patients who exhibit only increased levels of markers of myocardial injury without any symptoms are divided into 1 level and do not need corticosteroid treatment, however, monitoring of cardiac parameters needs to be continued. The results of this study may help clinicians identify, early in the course of the disease, which patients with level 1 will continue to develop symptoms and which patients with symptoms will continue to progress to death. In view of the very high mortality rate of PD-1 inhibitor-related myocarditis, these results may help us to stay aware of specific patients and provide more appropriate treatments in the early stages of disease deterioration.

This study also has some limitations. First of all, this is a single-center retrospective study. Although we want to clarify the specific probability of myocardial injury after PD-1 inhibitor treatment, a large proportion of the data is incomplete,

and there are many deviations. Laboratory indicators and ECG indicators are complete, but there are missing data on cardiac ultrasound. Thus, we used the mean instead. This led to a shift in the research results. Second, we cannot completely rule out myocardial damage caused by other drugs, such as chemotherapy drugs, such as paclitaxel and platinum, although these drugs are rarely reported to cause myocardial damage, at the same time, we cannot completely rule out myocardial infarction, stress cardiomyopathy, and other causes of myocardial injury in these patients because of the lack of very complete clinical examination results. Third, the small sample size and information bias may affect the results of our study. Further research should be conducted with larger sample size and minimize the information bias for more reliable results.

## Conclusion

In patients with myocardial injury after PD-1 inhibitor treatment, NT-proBNP is the superior parameter of choice to predict the likelihood of developing cardiovascular symptoms, whereas, in symptomatic patients, hsTnT is superior to other cardiac parameters and is associated with the development of death.

Chimeric antigen receptor T-cell (CAR T) therapy is a revolutionary personalized therapy that has significantly impacted the treatment of patients with hematologic malignancies refractory to other therapies. Cytokine release syndrome (CRS) is a major side effect of CAR T therapy that can occur in 70–90% of patients, with roughly 40% of patients at grade 2 or higher. CRS can cause an intense inflammatory state leading to cardiovascular complications, including troponin elevation, arrhythmias, hemodynamic instability, and depressed left ventricular systolic function. There are currently no standardized guidelines for the management of cardiovascular complications due to CAR T therapy, but systematic practice patterns are emerging. In this review, we contextualize the history and indications of CAR T cell therapy, side effects related to this treatment, strategies to optimize the cardiovascular health prior to CAR T and the management of cardiovascular complications related to CRS. We analyze the existing data and discuss potential future approaches.

## KEYWORDS

chimeric antigen receptor (CAR T), cardio-oncology, immunotherapy, cytokine release syndrome (CRS), cellular therapy, cardiovascular disease

## Introduction

The power of the immune system in treating neoplastic diseases has long been recognized in the medical community. However, starting from adoptive cell transfer, the precursor of CAR T, various cardiovascular toxic side effects have also been identified. Herein we review the available data, and propose a strategy for prevention, surveillance and management of cardiovascular toxicity in patients receiving immune cellular therapies.

## Adoptive cell transfer

Adoptively acquired immunity is the process through which active immune tissues are transferred from a donor to a recipient (1–3). Initial studies performed in the 1950's demonstrated in mouse that immune tissue (i.e., spleen or lymph nodes) but not antigens or peripheral cells from a primary transplant tolerant host induced sustained resistance to rejection in a secondary host (1). In a landmark paper published in 1957, E. Donnall Thomas and colleagues demonstrated a sustained response after bone marrow infusion in several patients with bone marrow deficiency following radiation and chemotherapy (3). This led to the first allogeneic bone marrow transplantations in the early 1960s, using bone marrow from twin siblings. With the subsequent development of autologous stem cell transplantation, adoptive cellular therapies have become a mainstay in the treatment of hematologic malignancies (4).

## Modern development of cellular therapies

Following the historic success of bone marrow transplantation, the next phase of adoptive cell transfer came in the 1980s with the emergence of tumor-infiltrating lymphocytes (TIL) (5–8). In this therapy, B- and T-cells isolated from the tumor biopsy are expanded in a laboratory and subsequently infused back into the original host after a dose of chemotherapy (5, 6). TIL were combined with interleukin-2, a key cytokine in the proliferation and differentiation of effector T cells, to enhance their antitumor effects (5, 6).

With the advent of gene-transfer techniques, the potential of peripheral blood T cells was further harnessed through genetic modifications that increase their specificity and augment their function (9, 10). These “first-generation” genetically modified T cells were engineered to express a chimeric antigen

receptor (CAR)—composed of an extracellular single-chain variable fragment (scFv) that serves as the targeting moiety, a transmembrane spacer, and intracellular signaling/activation domain(s)—to target surface-exposed tumor-associated antigens (10–12). Over time, CARs evolved to more complex “second-” and “third-generation” CARs that have augmented T cell persistence and proliferation (13–16).

## Chimeric antigen receptor T-cell therapy mechanism and indications

The development of CAR T cell therapy triggered a paradigm shift in cancer immunotherapy, demonstrating remarkable success particularly in CD-19 expressing malignancies, as the first genetically engineered personalized therapy option. This therapeutic option has become a viable and commercially available treatment option for several hematologic malignancies (Table 1). Promising results emerged from the initial CAR T trials of tisagenlecleucel (tisa-cel) and axicabtagene ciloleucel (axi-cel) in 2017 (17). Tisa-cel was the first anti-CD-19 CAR T product approved by the Food and Drug Administration (FDA), for patients up to 25 years of age with relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL) in 2017 (17). Axi-cel, an anti-CD-19 targeting CAR T-cell, approval followed soon after in 2017 for patients with relapsed or refractory diffuse large B-cell lymphoma (18). Axi-cel was subsequently also approved for the management of patients with relapsed or refractory follicular lymphoma after 2 prior lines of therapy (19). Since then, the FDA has approved 6 total CAR T therapies for the treatment of hematologic malignancies, including lisocabtagene maraleucel (liso-cel) for relapsed or refractory diffuse large B-cell lymphoma, brexucabtagene autoleucel (brexu-cel) for relapsed or refractory mantle cell lymphoma and relapsed or refractory ALL, and idecabtagene vicleucel (ide-cel) and ciltacabtagene autoleucel (cita-cel) for relapsed and refractory multiple myeloma (18, 20–23) (Table 1). Responses for all these agents average around 60 to 80% with complete remissions achieved in approximately 40 to 60% of the patients (17–19, 21, 22). These results are especially striking given the failure of conventional chemotherapy, including high-dose chemotherapy and stem cell transplantation in this population.

## Chimeric antigen receptor T-cell therapy induction and administration

The administration of CAR T requires the identification of optimal patients who would generally be considered healthy and fit to undergo this procedure. While there is no established consensus on the optimal patient profile that would be considered suitable, various guidelines suggest

---

Abbreviations: ALL, acute lymphocytic leukemia; CAD, coronary artery disease; CAR T-cell, chimeric antigen receptor T-cell; CAR NK-cell, chimeric antigen receptor natural killer cell; CEA, carcinoembryonic antigen; CHF, congestive heart failure; CMR, cardiac magnetic resonance; CRS, cytokine release syndrome; CV, cardiovascular; CVD, cardiovascular disease; ECG, electrocardiogram; FAP, fibroblast activation protein; FDA, Food and Drug Administration; GD2, disialoganglioside 2; HER2, human epidermal growth factor receptor 2; HLH, hemophagocytic lymphohistiocytosis; ICANS, immune cell-associated neurotoxicity syndrome; IFN- $\gamma$ , interferon-gamma; IL, interleukin; L1CAM, L1 cell adhesion molecule; MCP-1, monocyte chemoattractant protein-1; MI, myocardial infarction; MIP-1 $\beta$ , macrophage inflammatory protein-1 beta; REMS, risk evaluation and mitigation strategy; TIL, tumor-infiltrating lymphocytes; TNF $\alpha$ , tumor necrosis factor alpha; TTE, transthoracic echocardiogram.

**TABLE 1** Summary of current FDA-approved CAR T generic names, trade names, and indications.

CAR product (generic name)	CAR product (trade name)	Indication(s)
Tisagenlecleucel	Kymriah	Acute lymphoblastic leukemia, B-cell lymphoma (17)
Axicabtagene ciloleucel	Yescarta	B-cell lymphoma, follicular lymphoma (18, 19)
Lisocabtagene maraleucel	Breyanzi	B-cell lymphoma (20)
Brexucabtagene autoleucel	Tecartus	Mantle cell lymphoma (21)
Idecabtagene vicleucel	Abecma	Multiple myeloma (22)
Ciltacabtagene autoleucel (cita-cel)	Carvykti	Multiple myeloma (23)

CAR, chimeric antigen receptor.

utilizing established fitness and morbidity scores to determine eligibility (24–26). After harvesting the peripheral blood product through a routine apheresis procedure, the cells typically require processing and manufacturing which can take up to 4–6 weeks. During this interval, patients frequently require “bridging therapy” to ensure that they do not have rapid and symptomatic disease progression. Following successful manufacturing and receipt of the product, patients undergo lymphodepleting chemotherapy typically with fludarabine and cyclophosphamide over 3 days for up to a week prior to reinfusion of the cells. Patients are subsequently monitored closely for the development of cytokine release syndrome (CRS) and neurotoxicity which can manifest for approximately the first month after reinfusion of cells (24, 25). Because of the risks noted with CRS, patients must enter a risk evaluation and mitigation strategy (REMS) program and stay within 2 h of the CAR T center for the first month and must not drive for 2 months following CAR T.

## Immune cell-related adverse events

Robust systemic release of a high level of cytokines following overwhelming T cell activation as well as specific interactions between the CAR and its target antigen expressed by non-malignant cells are two mechanisms thought to mediate CAR T toxicities (27). One of the most common CAR T cell-related adverse events is CRS. CRS is a multisystem inflammatory response mediated by a surge of cytokines triggered by an infusion of CAR T cells. Among other toxic phenomena, CRS, in particular, affects 37–93% of patients with lymphoma (28), and 77–93% of patients with leukemia (28–31). Clinical manifestations can range from fevers and constitutional

symptoms to hypoxia, hypotension, end-organ damage, and even sepsis-like syndrome or death in severe cases (29). CRS is thought to result from widespread simultaneous activation of T-cells and release of cytokines and chemokines (30, 32). CRS has been associated with elevation of interleukin (IL)-6, IL-8, IL-10, IL-15, GM-CSF, interferon (IFN)- $\gamma$ , MCP-1, MIP-1b, ferritin, CRP, and in severe cases soluble IL-2 receptor (28, 33). Management includes supportive care and antipyretics in mild cases, administration of IL-6-receptor antagonists like tocilizumab in moderate CRS or those not responding to supportive care, and corticosteroids like dexamethasone in more severe cases of CRS (34, 35). CRS can occasionally mimic macrophage activation syndrome (MAS) or hemophagocytic lymphohistiocytosis (HLH) in severe cases, which is often treated with anakinra, an IL-1 receptor antagonist, if the above measures are not effective (36–39). Serum inflammatory markers (acute phase reactants) including c-reactive protein (CRP) and ferritin may be followed clinically to help aid in prediction of impending CRS or to monitor response to therapy, though cytokine levels are not often readily available in real time (39).

CRS may contribute to the development of immune cell-associated neurotoxicity syndrome (ICANS), which can manifest along a spectrum from mild delirium with confusion to cerebral edema, seizures, and even death (34, 40). Cardiovascular manifestations of CRS Although the underlying mechanism of ICANS is incompletely understood compared to CRS, studies have also shown a correlation with elevated levels of inflammatory cytokines like IL-6, IFN- $\gamma$  and TNF $\alpha$  (33, 41, 42). These signals are postulated to cause endothelial damage and activation with disruption of the blood brain barrier and capillary leak. It requires careful monitoring, frequent assessments, and promptly initiated therapy. ICANS has also been associated with sinus bradycardia that is often self-limited without need for intervention but should be monitored closely (43). Other constitutional, hematologic, renal, gastrointestinal, and dermatologic toxicities have also been observed (28, 41, 44–46).

## Cardiovascular complications of cellular immunotherapies

While there has been a consistent trend of improvement in the survival following both autologous and allogeneic hematopoietic cell transplantation bone marrow transplant therapies decade over decade (47, 48), cardiovascular toxicities (49) continue to be frequent complications, along with infections and graft vs. host disease. This has resulted in evolving practice guidelines targeting preventive evaluations pretransplant, monitoring peri-transplant, and surveillance in long term survivors (50, 51). With regard to CAR T therapy, the current information about cardiovascular side

effects related to CAR T therapies is limited to a few retrospective studies (Table 2), but concepts established for other adoptive cell transfers likely apply. In particular, with the growing prevalence of cardiovascular disease combined with the increase in available CAR T cell therapies for the treatment of hematologic malignancies, attempting to understand the mechanisms of these complications is essential as this may help guide interventions.

The impact of CAR T cell therapy on the cardiovascular system manifests as hemodynamic compromise, myocardial injury/dysfunction, and/or cardiac arrhythmias (60, 61). There is also the potential for pericardial complications, such as in a case report (62) describing a patient with high-grade lymphoma who developed a pericardial effusion and tamponade with cardiogenic shock after CAR T therapy. Higher-grade CRS appears to be linked to adverse cardiovascular events of all types. This is likely driven by the release of inflammatory cytokines into the bloodstream with CAR T therapy, particularly the secretion of interleukin-6 (IL-6). This cytokine is a mediator of systemic inflammation, leading to hemodynamic compromise and even circulatory collapse in CRS. Of the studies published so far in patients treated with CAR T cell therapy, cardiovascular monitoring was performed in 3 pediatric studies and 5 adult studies (52–59). All studies in adult populations were retrospective, single-center observational cohort studies. Across all studies, cardiovascular complications have been inconsistently monitored. In children, transient and reversible hypotension in the setting of high-grade CRS was more commonly noted. In studies that monitored for cardiovascular complications in adults, the most frequently observed were cardiac arrhythmias and heart failure, albeit with relatively low event rates overall. Interestingly, preexisting cardiovascular disease (including heart failure) has not been shown to be reliably associated with the development of cardiovascular complications after CAR T cell therapy in one cohort study (57). In contrast, in another cohort study (55), troponin elevation was notably associated with cardiovascular adverse events in patients undergoing CAR T cell therapy. The patients with troponin elevation in this study were older and had more traditional cardiovascular risk factors. In both these cohort studies cardiovascular complications occurred with increased frequency at higher grades of CRS (2 or greater). As such, additional studies in larger cohorts are needed to establish risk factors, biomarker elevation patterns, imaging findings, event rates, and outcomes after CAR T cell therapy.

## CRS monitoring and grading

Most patients undergoing CAR T can be managed on the regular cell therapy hospital floor with only a minority requiring ICU care, but close monitoring and specialty care is. due to rapid

onset of CRS, it is recommended that this therapy is given at a specialized center with CAR T experience and credentialing.

Grading of CRS is now done per the American Society of Transplantation and Cellular Therapy (ASTCT) consensus guidelines (Table 3) (34).

## CRS management

Rates of CRS and median time to onset vary depending on the particular CAR T product and disease burden. For example, in the KarMMa study of ide-cel for relapsed/refractory multiple myeloma (22), CRS was seen in 84% of patients, but most cases were only grade 1 or 2, with only 5% of patients developing grade 3–5. Median time to onset of CRS in the KarMMa study was 1 day (range 1–12 days) with a median duration of 5 days (range 1–63).

Management of CRS required tocilizumab in 52% patients, but only 15% required glucocorticoids (22, 63). On the other hand, in the Zuma-1 study of axi-cel for relapsed/refractory large B-cell lymphomas, CRS was a nearly universal side effect, with 93% of patients experiencing any grade CRS and 11% with grade 3 or higher, and hypotension was seen in 63%, tachycardia in 40%, and hypoxia in 34% (64). The median time to onset of CRS was 2 days (range 1–12) with a median duration of 8 days (65). All patients had resolution of their CRS, except for one patient who died from complications of HLH, and another patient who died of cardiac arrest with ongoing CRS. Tocilizumab was given in 43% and corticosteroids were required in 27% of Zuma-1 patients; however, more recently the FDA has issued a new label change for axi-cel allowing the prophylactic use of 3 days of corticosteroids based on a study showing much less severe CRS and ICANS without impairment of lymphoma response rates (66). The decision regarding inpatient vs. outpatient care and aggressive early therapy vs. minimal therapy for CRS is not only made based on the track record of the particular CAR T product but also based on risk factors such as age, frailty, and tumor burden, as higher tumor burden consistently correlates with increased incidence and severity of CRS (67).

## Surveillance for cardiovascular toxicity

At our institution, cardiovascular (CV) surveillance for CAR-T therapy begins with CV risk stratification prior to infusion. Patients with CV comorbidities (especially heart failure, coronary artery disease, arrhythmias) or new/worsening CV symptoms (i.e., chest pain, dyspnea on exertion, lower extremity edema) represent a high CV risk group. Older age and prior cardiotoxic cancer therapy (i.e., anthracyclines, chest radiation) may also raise the risk of CV toxicity after treatment (68). In these high CV

TABLE 2 Summary of pediatric and adult studies investigated cardiovascular complications and CAR T-cell therapy.

Study specific parameters: <sup>a</sup> Pediatric population; <sup>b</sup> Adult population; <sup>c</sup> Cardiomyopathy, defined as decreased left ventricular systolic function requiring milrinone; <sup>d</sup> Cardiac dysfunction, defined as either an echocardiographic decrease of  $\geq 10\%$  in ejection fraction or  $\geq 5\%$  in shortening fraction from normal baseline ejection fraction  $> 55\%$  or shortening fraction  $> 28\%$ ; <sup>e</sup> Cardiac dysfunction, defined as either a  $> 10\%$  absolute decrease in LVEF compared with baseline or new-onset LV systolic dysfunction (LVEF  $< 50\%$ ); <sup>f</sup> Cardiovascular mortality, defined as a combination of death due to heart failure, cardiogenic shock, cardiac arrest, or an arrhythmia; <sup>g</sup> Arrhythmia, defined as new-onset supraventricular tachycardia, atrial fibrillation, or atrial flutter requiring intervention; <sup>h</sup> Heart failure, defined as clinical signs of heart failure on physical examination, laboratory or imaging or radiographic findings of heart failure (B-type natriuretic peptide or N-terminal pro-B-type natriuretic peptide, Kerley B-lines or pulmonary edema, pleural effusion, decreased left ventricular ejection fraction, and initiation of new treatment for heart failure (pharmacological therapies such as diuretic agents and/or mechanical support); <sup>i</sup> Arrhythmia, defined as atrial fibrillation, ventricular tachycardia; <sup>j</sup> Arrhythmia, defined as non-sustained ventricular tachycardia, atrial fibrillation; <sup>k</sup> Myocardial infarction, defined as angina or anginal equivalent symptoms with cardiac enzyme elevation, with or without EKG/echocardiographic changes.

PubMed search performed using the following terms: Chimeric antigen receptor; cardiovascular; cytokine release syndrome.

TABLE 3 American Society of Blood and Marrow Transplantation (ASBMT) consensus grading of cytokine release syndrome (CRS) severity (34).

Cytokine release syndrome parameter	Grade 1	Grade 2	Grade 3	Grade 4
Fever	Temperature $\geq 38^{\circ}\text{C}$	Temperature $\geq 38^{\circ}\text{C}$	Temperature $\geq 38^{\circ}\text{C}$	Temperature $\geq 38^{\circ}\text{C}$
With				
Hypotension	None	Not requiring vasopressors	Requiring one vasopressor with or without vasopressin	Requiring multiple vasopressors (excluding vasopressin)
And/or*				
Hypoxia	None	Requiring low-flow nasal cannula or blow-by	Requiring high-flow nasal cannula, facemask, nonrebreather mask, or Venturi mask	Requiring positive pressure (e.g., CPAP, BiPAP, intubation, and mechanical ventilation)

CPAP, Continuous Positive Airway Pressure; BiPAP, Bilevel Positive Airway Pressure.

\*CRS grade is determined by the more severe event: hypotension or hypoxia not attributable to any other cause.

Fever is defined as temperature  $\geq 38^{\circ}\text{C}$  not attributable to any other cause. In patients who have CRS then receive antipyretic or anti-cytokine therapy such as tocilizumab or steroids, fever is no longer required to grade subsequent CRS severity.

Low-flow nasal cannula is defined as oxygen delivered at  $\leq 6$  L/min. Lowflow also includes blow-by oxygen delivery, sometimes used in pediatrics. High-flow nasal cannula is defined as oxygen delivered at  $> 6$  L/min.

risk patients, standard baseline testing should include a 12-lead electrocardiogram, cardiac biomarkers (troponin, NT-proBNP), and transthoracic echocardiography. In some cases, cardiac MRI may clarify features of cardiac structure and/or function that would guide optimization of CV therapy. Cardioprotective therapies such as beta-blockers and renin-angiotensin-aldosterone system blockers, diuretics, and/or antiarrhythmics should be utilized as clinically indicated. In addition, any patient with the above cardiovascular comorbidities, and whose baseline electrocardiogram or transthoracic echocardiogram is abnormal, should

be considered for cardio-oncology referral pre-CAR T therapy.

Inpatient monitoring after CAR-T infusion is strongly recommended for patients with increased baseline CV risk. Figure 1 shows our institutional algorithm for surveillance and monitoring in this population. Standard monitoring protocols after CAR-T infusion include daily blood counts and metabolic profiling, physical examination, and screening for CRS (69). Patients at high baseline CV risk should additionally be monitored on telemetry with close monitoring of oral and intravenous fluid input, urine output, and daily

body weight measurement. Given the observed association between CRS and CV events after CAR-T (55, 57), all patients with grade 3 or 4 CRS should also be placed on these CV monitoring protocols.

The utility of routine cardiac biomarker testing for detection of CV toxicity after CAR-T is uncertain. Where there is clinical suspicion for a CV event after CAR-T infusion based on symptoms or monitoring, initial evaluation should include cardiac biomarkers (troponin, NT-proBNP), 12-lead electrocardiogram (ECG), and transthoracic echocardiography (TTE). Cardio-oncology consultation should be obtained, if available, to direct further diagnostic evaluation and management.

Data are limited regarding the optimal surveillance and testing protocol for patients undergoing CAR T cell therapy. Current standards of practice have been previously published by Hayden et al. (26), Ghosh et al. (60), and Totzeck et al. (70), with similar approaches to our institution and each other with regard to screening and surveillance while on CAR T therapy. Ghosh et al. propose that all patients undergo baseline cardiac magnetic resonance imaging (CMR) with follow-up CMR in patients with abnormal biomarkers, ECG, and/or TTE. We generally agree with these publications on the initial evaluation of patients after a cardiovascular event with CAR-T infusion, including cardiac blood biomarkers (troponin, NT-proBNP), ECG, and TTE, with judicious use of CMR in appropriate cases. By contrast, there is some variability in the post-CAR T surveillance and monitoring approaches proposed by the other consensus approaches. For example, Ghosh et al. recommend for all patients to follow-up with cardio-oncology 3 months after CAR T cell therapy, whereas the other two consensus recommendations propose a 7-day follow-up visit. We propose a patient-specific approach depending on the type of cardiovascular event that patient experienced. The utility of monitoring for late effects (i.e., at 3 months post CAR-T and beyond) and the potential for long-term CV consequences of CAR-T itself stand out as areas for future study.

## Future directions

Current targets of CAR T are malignant immune cells, but new targets continue to develop. There has been an expanding focus on targeting solid tumors, and overall, nearly 600 clinical trials are underway (71–73). Multiple new endeavors are focusing on solid tumor surface antigens such as carcinoembryonic antigen (CEA), ganglioside GD2 subtype, mesothelin, interleukin-13 receptor  $\alpha$  (IL-13R $\alpha$ ), human epidermal growth factor receptor 2 (HER2), fibroblast activation protein (FAP), and L1 cell adhesion molecule (L1CAM) (16, 74–79).

Multiple trials are currently ongoing evaluating various CAR T products in different disease entities including allogeneic

products utilizing various T-cell and NK-cell engineering and manufacturing procedures. Moreover, the well-documented side effects of CAR T—most notably, CRS—have spurred the recent discussion surrounding CAR NK-cell therapy, a potential avenue to mitigate the systemic immune effects (73). CAR T has been shown to effectively target and remove activated cardiac fibroblasts in mice, suggesting potential applications to address myocardial scar and fibrosis (80, 81). At the same time, early signals have raised concerns about the unique dangers of systemic immune effects in patients with preceding cardiovascular diseases or cardiovascular risks, with limited information about cardiotoxicity available from the initial CAR T trials. Clinical practice guidelines are emerging to address immune cell-related adverse events (82). Next steps also include validated risk prediction tools for cardiovascular complications after CAR-T, elucidate mechanisms of these immune-mediated complications, development of preventative therapies by integrating timelines of cardiac blood biomarkers and immunophenotyping in this population.

## Conclusions

The rapid development of immunocellular personalized therapeutic modalities is creating unprecedented opportunities for treatment of cancers. To optimize the cardiovascular outcomes in patients treated with CAR T several lessons learned from other anticancer therapies and from early CAR T studies may be beneficial. While early studies have established the specific indications for these therapies, cardiovascular risk profiles will need to be defined further during their real-life application. The awareness of interactions between the cardiovascular risks, underlying cardiovascular problems and the cytokine release syndrome is prompting the definition of systematic assessments before and during CAR T therapy. Yet unknown potential latent effects, such as vascular inflammation seen after other immunotherapeutic interventions (i.e., immune checkpoint inhibitor therapies) will need to be taken in consideration for long-term cardiovascular surveillance. Inclusion of cardiovascular endpoints in trials, as well as broad collaborative, prospective clinical registries have the potential to provide new information about these risks. And not the least, the further investigation of such observations in targeted research studies has the potential to refine this technology and expand its safe applicability.

## Author contributions

AR and VZ organized the outline and the components of the manuscript, as well. AR, AS, and ME performed an extensive literature search of cardiovascular disease and chimeric antigen receptor T cell therapy. PR, LA, and FA

wrote individual sections on CAR T therapy and provided feedback on the manuscript. AC, SV, and KZ created the figure and wrote the section on surveillance and monitoring. All authors contributed to the writing efforts and the editing of this manuscript.

## Funding

VZ received support from the Cancer Prevention Research Institute of Texas (RP180404).

## Conflict of interest

Author FA has provided consultancy to: Genentech, AstraZeneca, Abbvie, Janssen, Pharmacyclics, Gilead sciences,

Kite pharma, Celgene, Karyopharm, MEI Pharma, Verastem, Incyte, Beigene, Johnson and Johnson, Dava Oncology, BMS, Merck, Cardinal Health, ADCT therapeutics, and Epizyme.

The remaining authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

**Background:** Management of coronary artery disease (CAD) is unique and challenging in cancer patients. However, little is known about the outcomes of using BMS or DES in these patients. This study aimed to compare the outcomes of percutaneous coronary intervention (PCI) in cancer patients who were treated with bare metal stents (BMS) vs. drug-eluting stents (DES).

**Methods:** We identified cancer patients who underwent PCI using BMS or DES between 2013 and 2020. Outcomes of interest were overall survival (OS) and the number of revascularizations. The Kaplan–Meier method was used to estimate the survival probability. Multivariate Cox regression models were utilized to compare OS between BMS and DES.

**Results:** We included 346 cancer patients who underwent PCI with a median follow-up of 34.1 months (95% CI, 28.4–38.7). Among these, 42 patients were treated with BMS (12.1%) and 304 with DES (87.9%). Age and gender were similar between the BMS and DES groups ( $p = 0.09$  and  $0.93$ , respectively). DES use was more frequent in the white race, while black patients had more BMS ( $p = 0.03$ ). The use of DES was more common in patients with NSTEMI ( $p = 0.03$ ). The median survival was 46 months (95% CI, 34–66). There was no significant difference in the number of revascularizations between the BMS and DES groups ( $p = 0.43$ ). There was no significant difference in OS between the BMS and DES groups in multivariate analysis ( $p = 0.26$ ). In addition, independent predictors for worse survival included age  $> 65$  years, BMI  $\leq 25$  g/m<sup>2</sup>, hemoglobin level  $\leq 12$  g/dL, and initial presentation with NSTEMI.

**Conclusions:** In our study, several revascularizations and survival were similar between cancer patients with CAD treated with BMS and DES. This finding

suggests that DES use is not associated with an increased risk for stent thrombosis, and as cancer survival improves, there may be a more significant role for DES.

## Introduction

Cardiovascular disease and cancer frequently coexist in an increasingly aging population and share the same risk factors (1). They are also the leading causes of death in developed countries, accounting for two-thirds of disease-related mortality (1). Despite the increased prevalence of thrombocytopenia and bleeding tendencies, cancer is often associated with a hypercoagulable state with increased platelet activation and aggregation. In addition, many chemotherapeutic agents are associated with angina, myocardial infarction (MI), and acceleration of pre-existing coronary artery disease (CAD), while radiotherapy is associated with CAD through direct endothelial injury (2–4). All the aforementioned factors make the management of cancer patients' CAD unique as well as challenging.

A history of cancer is independently associated with an increased risk of major adverse cardiovascular events (MACE) (5–7). The current generation of drug-eluting stents (DES) has been proven to reduce the risk of restenosis and stent thrombosis compared to bare-metal stents (BMS). However, data suggesting the preference of DES over BMS in the cancer population are lacking. The perceived need for a shorter course of dual antiplatelet treatment (DAPT) used to make the use of BMS an attractive alternative, particularly in patients with increased bleeding risk and an expectant need for cancer-directed surgery and/or procedures (8, 9).

There are limited data on the outcomes of cancer patients requiring PCI when directly comparing BMS with DES. Additionally, most randomized controlled trials making such comparisons exclude patients with active malignancy and treatment. With a growing number of patients with cancer, it is essential to study the outcomes of different types of stents and the duration of antiplatelet agents (10). The current study examines clinical and procedural characteristics and clinical outcomes in cancer patients with CAD treated with BMS vs. DES.

## Materials and methods

### Patient population

This was a single-center, retrospective, observational study approved by the MD Anderson Cancer Center Institutional Review Board. The requirement to obtain informed consent was waived, and the data were deidentified. All cancer patients who underwent PCI between January 2013 and December 2020 were included. Patients were further divided into two groups based on the type of intervention performed using either BMS or DES. Patients treated with balloon angioplasty alone were excluded. The decision to treat a patient with either of these strategies was based on the clinical characteristics of the individual patient. It was left to the discretion of the treating physicians.

Patient characteristics were collected using electronic medical records, including age, sex, race, body mass index, indication for primary PCI, comorbidities (history of diabetes mellitus, hypertension, hyperlipidemia, end-stage renal disease, peripheral vascular disease, stroke, or transient ischemic attack, previous coronary artery bypass graft, and PCI, etc.), as well as laboratory variables (hemoglobin, platelet count, creatinine, lipid panel, troponin, and B type natriuretic peptide/BNP, etc.), type of malignancy (solid vs. hematological), and intracoronary imaging used (intravascular ultrasound/IVUS and optical coherence tomography/OCT), as MD Anderson Catheterization laboratory is not an ST-elevation myocardial infarction (STEMI) receiving center, so these patients were not included. All other indications of revascularizations include "cardiomyopathy," "positive stress test," "unstable angina," "non STEMI," and "angina with prior history of CAD." Propensity score matching was conducted to select patients treated with BMS and comparable patients treated with DES. Furthermore, information related to primary outcomes was collected. The term "number of revascularizations" was defined by the total number of revascularizations needed for either the target vessel stented with either BMS or DES during the index procedure or for other arteries.

## Outcomes

The primary endpoints included all-cause mortality and the number of revascularizations at the end of the follow-up period, while the secondary outcome was cardiovascular death.

## Statistical analysis

Continuous variables were described as means ± standard deviations (SDs) or medians with interquartile ranges (IQRs). As appropriate, categorical variables were described as counts and percentages. Patient characteristics were compared between BMS and DES by a two-sample *t*-test or Wilcoxon rank-sum test for continuous variables and a Chi-square test or Fisher's exact test for categorical variables. Overall, survival time was defined as the interval between index PCI intervention and death. It was determined at the last follow-up if the patient was alive during the follow-up. The Kaplan–Meier method was used to estimate the survival probability. Univariate and multivariate Cox regression models were used to compare BMS and DES overall survival. The multivariate logistic regression model initially included covariates with a significant or marginally significant *p*-value based on univariate logistic regression analysis. The stepwise selection method was then utilized to include significant variables in the multivariate model. The propensity score, the predicted probability of receiving BMS, was calculated using a multivariate logistic regression model including significant factors. 1:1 propensity score matching and a 1:2 propensity score matching were conducted to select patients treated with BMS and comparable patients treated with DES using a one-to-many match macro using a greedy algorithm. A univariate Cox regression model was utilized to compare overall survival between BMS and DES in propensity score-matched cohorts. A *p* < 0.05 indicates

**FIGURE 1**

statistical significance. For data analysis, SAS version 9.4 (SAS Institute, Inc., Cary, North Carolina) was used.

## Results

### Baseline characteristics

The study included 346 CAD cancer patients treated with BMS ( $n = 42$ ) or DES ( $n = 304$ ), while patients

treated with POBA ( $n = 9$ ) were excluded (Table 1). The median follow-up time, estimated by the reverse of the Kaplan–Meier method, was 34.1 months (95% CI, 28.4–38.7). The median survival time was 46.2 months (95% CI, 34.0–66.0) (Figures 1, 2). Patient characteristics of the intervention (BMS vs. DES) are summarized in Table 1. Some variables showed significant differences between the BMS and DES groups: BMS was more prevalent in blacks, while DES was more commonly seen in whites. Lipid panels, including

TABLE 2 Univariate Cox model (on overall survival time); with 346 who performed BMS or DES (147 deaths).

Including 323 patients with either BMS or DES considering age, hemoglobin (12 g/dL as a cutoff value), intervention, BMI, and an indication of NSTEMI.

cholesterol and mean LDL, were higher in the BMS group. The BMS group had a higher prevalence of family history of premature CAD, while those treated with DES had a significantly increased number of prior MI and PCI. DES use was more common in patients with non-ST segment elevation MI (NSTEMI).

## Univariate Cox analysis results

Univariate analysis results are presented in Table 2. Age, higher INR, lower hemoglobin, lower body mass index (BMI), absence of hypertension, and primary PCI indication of NSTEMI were significantly associated with an increased risk of death.

## Multivariate Cox analysis results

A multivariate Cox model initially considered the age at intervention, INR group, hemoglobin group, family

history of premature CAD, chronic lung disease, BMI group, and an indication of primary PCI (abnormal stress test or NSTEMI). Age, hemoglobin, BMI, and indication of NSTEMI remained significant in multivariate analysis. Therefore, multivariate models, including age group, hemoglobin group (using 12 g/dl as a cutoff value), BMI group, and an indication of NSTEMI, are presented in [Table 3](#). After adjusting for age, hemoglobin, BMI, and indication of NSTEMI, BMS and DES did not show a significant difference in overall survival.

2019	0 (0)	49 (100)
2020	1 (4.3)	22 (95.7)

## Propensity score matching

Some patients were treated with BMS, while others with DES, and these interventions were not randomly allocated. To make a fair comparison between BMS and DES in outcomes, we calculated the propensity score using a logistic regression model to predict being treated with BMS. The logistic regression model initially considered significant or marginally significant variables in univariate logistic regression models (age at intervention, family history of premature CAD, race, prior MI, and diabetes). The stepwise selection method selected family history of premature CAD, race, and diabetes in the final multivariate logistic regression model. Using this model, we calculated the propensity score as the predicted probability of receiving BMS for given covariates. Using these propensity scores, we selected a 1:1 propensity score-matched cohorts (38 BMS vs. 38 DES) and a 1:2 propensity score-matched cohorts (33 BMS vs. 66 DES). In these cohorts, BMS and DES did not show significant differences in overall survival ([Tables 4a,b](#)).

The “number of revascularizations” was compared between the two groups: BMS vs. DES ([Table 5a](#)). Propensity score matching was also performed for the “number of revascularizations” ([Tables 5b,c](#)).

## Secondary outcomes and other statistical analysis

Univariate Fine-Gray models, considering cardiovascular-specific death as an event of interest and death as a competing risk event, revealed no significant difference in cardiovascular outcomes between BMS vs. DES ([Table 6](#)). Detailed cancer characteristics for patients in the BMS and DES groups are provided in [Table 7](#). The number of patients

who underwent BMS and DES each year during the study duration (2013–2020) is provided in [Table 8](#). A descriptive patient flowchart for inclusion in the study is provided in [Figure 3](#).

## Discussion

Our study showed that 1) the number of revascularizations (including target and other vessels) in cancer patients with CAD treated with BMS vs. DES was similar during the follow-up period, and 2) the all-cause mortality between BMS and DES did not differ significantly. These are important findings since cancer and cardiovascular disease are the most prevalent diseases worldwide. Data on outcomes after percutaneous intervention in these patients are scant, and the evidence-based treatment regimen for CAD in this group of patients is not well established ([11–13](#)).

Several comorbid conditions affect patients with cancer, which influence their treatment in the setting of PCI. While cancer and its treatment can predispose patients to bleeding tendencies and thrombocytopenia, neoplasia by itself is a pro-coagulant state ([14](#)). This poses a unique challenge and highlights the need to evaluate thrombosis and bleeding risks carefully. In the setting of PCI, this information has a tremendous impact on the options for stenting and antiplatelet therapy ([14](#)). Several clinical studies have proven the superiority of DES over BMS in reducing the risk of restenosis and stent thrombosis compared with bare-metal stents (BMS) in non-cancer high-risk patients ([9](#)). In-stent restenosis, although of concern, may not be significant due to shorter-term survivorship from cancer. As cancer survival rates keep improving, the role of DES in improved restenosis becomes more important. A study using OCT to evaluate stent healing after DES placement showed adequate stent healing in cancer patients despite a shorter course of DAPT (<6 months) in 61% of them. Findings were matched with stent healing value for DES in non-cancer patients ([15](#)).

Another concern for DES use in cancer patients is stent thrombosis, given the need for a shorter course of antiplatelet therapy in selected cases ([16](#)). In our study, the number of revascularizations was similar between the DES and BMS groups. Hence, DES is likely not associated with increased thrombotic risk in the cancer patient population. The idea of abbreviated DAPT after BMS appeals to the high-risk group of cancer patients ([17](#)). With recent advancements, the current-generation DES now possesses a reduced stent strut thickness and a unique drug fast-release profile that results in less powerful inhibition of intimal hyperplasia and rapid reendothelialization of stent struts. Given these qualities, a shorter duration of DAPT seems more feasible ([18](#)).

Recently published trials showed that 1 month of DAPT after PCI followed by aspirin monotherapy was non-inferior to 6 or 12 months of full antiplatelet therapy ([18, 19](#)). Interestingly, there was no difference in the occurrence of major bleeding and stent thrombosis between both groups. Similar studies are needed in a cancer population. Currently, the latest American College of Cardiology/American Heart Association

(ACC/AHA) guidelines and European Society of Cardiology (ESC) guidelines still emphasize a class I recommendation for at least 6 months of DAPT in non-ACS for DES and 1 month for BMS, and 12 months of DAPT in ACS settings for both DES and BMS (20, 21). According to the ACC/AHA guidelines, discontinuation of aspirin may be considered 1–3 months after DES implantation with continued P2Y12 monotherapy in both stable ischemic heart disease (SIHD) and ACS patients (class 2a recommendation) (20). We believe future guidelines will continue to implement shorter courses of DAPT as more data supporting this becomes available, especially with advanced technology in stent development. This will favor DES use in such a high-risk cancer population.

Another important consideration is the increased requirement for anticoagulation in cancer patients due to their higher propensity for thrombosis and atrial fibrillation. The management of triple therapy in these patients poses its own challenges due to the high risk of bleeding and a decision

regarding the timing of re-initiation of chemotherapy (22, 23). A recent large study on a national database suggested superior outcomes in patients with cancer with a DES placed compared with those with a bare-metal stent (BMS) placed (8). However, this was driven by higher in-hospital mortality and increased bleeding events in the BMS group, signifying a selection bias to use BMS for sicker patients requiring early discontinuation of DAPT for various reasons, including initiation of cancer therapy due to advanced disease (24, 25). Although the choice of a stent in our study was at the treating physician's discretion after shared decision-making with the patient, a key difference in baseline characteristics between the two groups was an increased number of patients with NSTEMI in the DES group.

A significant interplay exists between cancer and CAD. Given a high bleeding risk in patients with cancer, shorter-duration DAPT and BMS were historically preferred in the setting of percutaneous coronary intervention. However, factors such as chronic inflammation and

chemotherapy/radiation-induced cardiotoxicity increase the risk of stent thrombosis and in-stent restenosis. Another important observation from this study is that in cancer patients, despite the increased inflammatory and prothrombotic state, the use of DES was not associated with a need for more revascularizations as compared to BMS. In a recent Italian registry, the use of BMS was extremely low, at 0.3 %, with the main reasons for BMS use being advanced age, ST-elevation myocardial infarction (STEMI), and physicians' perception of a high risk of bleeding (25).

Moreover, recent evidence from multiple studies suggests that shorter-duration DAPT is feasible with newer-generation DES and that percutaneous coronary intervention outcomes with the current generation of DES are better than with BMS (26, 27). Although the utilization of these stents in cancer patients is yet to be tested, in light of the current evidence, there is no reason for using BMS in any situation except for some cost-effectiveness. Moreover, the revolution of BMS vs. DES in our study indicates a stronger preference for using DES in the later years, with improvement in the design and generations of these stents.

Recent data suggest that routine use of intracoronary imaging leads to superior outcomes, which is paramount when shorter durations of DAPT are required (28–30). In our study, > 50% of the patients in either arm had IVUS as a part of their intervention, while almost 5% in BMS and 10% in DES underwent OCT. This highlights the role of optimizing PCI in this patient population, particularly given the increased likelihood that a shorter duration of DAPT may be required. This approach can avoid stent under-sizing and malapposition and residual untreated complications such as edge dissections, all of which may lead to worse outcomes, especially with a shorter duration of DAPT (13). When possible, bifurcation and overlapping stents should be avoided to reduce the risk of stent thrombosis (13).

## Study limitations

Our study included a large cohort of patients with cancer patients undergoing PCI with DES vs. BMS reported to date. However, it was a single-center retrospective observational study with known limitations, including relatively small sample size. Also, mortality data may be underestimated because we rely on our electronic medical records. Furthermore, the successful continuation of DAPT therapy in both arms could not be accurately confirmed due to the study's retrospective nature. Moreover, our study did not use the newest generations of stents, including zotarolimus-coated stents, polymer-free stents, nano-coated stents, etc., requiring shorter-term DAPT therapy. Some data regarding index procedure details, including the number of stents used and the type of target

vessel for revascularization, which can potentially affect the future need for revascularization, were not obtained and hence can affect the outcomes of the study. This calls for more detailed data collection for cancer patients in large-scale PCI registries to further validate the findings of our study.

## Conclusion

In conclusion, cancer patients with CAD treated with BMS had similar overall survival and need for revascularizations compared to patients treated with DES. Our study revealed no increased risk of stent thrombosis or restenosis as well as all-cause mortality in cancer patients when comparing BMS vs. DES. As cancer therapy continues to evolve, the survival of these patients is expected to increase. Hence, greater use of DES may benefit these patients over a longer follow-up period. As such, the choice of stents in these patients should factor in the stage of cancer, expectant survival, and overall prognosis.

## Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

## Ethics statement

The studies involving human participants were reviewed and approved by the MD Anderson Cancer Center Institutional Review Board. Written informed consent for participation was not required for this study in accordance with the national legislation and the institutional requirements.

## Author contributions

TA contributed to conception or design of the work, acquisition, analysis, or interpretation of data for the work, and drafting the work or revising it critically for important intellectual content. HP and AA contributed to the acquisition, analysis, or interpretation of data for the work, and drafting the work. EK contributed to revising it critically for important intellectual content. JS did analysis of the data and provided approval for publication of the content. KC, KM, KB, MC, and CG contributed to revising it critically for important intellectual content and final approval. CI contributed to revising it critically, provided final approval of publication, agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated, and

resolved. All authors contributed to the article and approved the submitted version.

## Funding

The statistical analysis work was supported in part by cancer center support Grant No. 24 (NCI Grant No. PA30 CA016672).

**Objective:** The aim of this article is to assess the risk and potential mechanisms of cardiovascular adverse events in patients treated with nilotinib or imatinib by conducting a systematic review, meta-analysis and integrative bioinformatics analysis.

**Materials and methods:** Three databases were systematically searched for studies published from inception to May 29, 2022. Differential expression analysis and weighted gene coexpression network analysis (WGCNA) were performed to search for modules of genes most associated with cardiotoxicity. Protein-protein interaction (PPI) network analysis was then performed to identify hub genes for the cardiotoxicity of nilotinib. Molecular docking was used to analyze the effects of rosuvastatin and aspirin on these targets.

**Results:** Patients treated with nilotinib as first-line treatment were associated with a higher risk of CAE (OR = 3.43 [95% CI 2.77–4.25]), CAD (OR = 5.30 [95% CI 3.85–7.29]), ACS (OR 2.7 [95% CI 1.60–4.54]), CVA (OR 5.76 [95% CI 2.84–11.28]), PAOD (OR 5.57 [95% CI 3.26–9.50]) and arrhythmia (OR 2.34 [1.17,4.67]) than those treated with imatinib, while no significant difference was found in the risk of HF (OR 1.40 [95% CI 0.42–4.69]) between the two groups. Patients who were treated with more than 600 mg daily dosage of nilotinib or followed up for more than 5 years had a higher risk of ACS and CVA. IL6, CXCL8, CCL2, SOD2, NFKBIA, and BIRC3 were identified as the top 6 hub genes in the magenta module (human cardiomyocyte samples) and were mainly enriched in the NOD-like receptor signaling pathway, IL-17 signaling pathway, TNF signaling pathway, lipid and atherosclerosis signaling pathway. TYROBP and CSF1R were identified as hub genes in the turquoise module (liver samples from *Mus musculus*). GSEA results showed that type II diabetes mellitus, B-cell receptor, apoptosis, insulin, natural killer cell mediated cytotoxicity,

were 94.5% (5). The rates of major (MMR) and deep (MR4) molecular responses were 96% and 83%, respectively (5).

Apart from hematological, musculoskeletal, gastrointestinal and subcutaneous toxicity, nilotinib can also lead to adverse effects different from those of imatinib, such as cardiovascular adverse events (1, 6). A total of 23.3% of patients have at least one arterial obstructive event, which suggests that cardiovascular toxicity remains a concern. Nilotinib (NILO) can cause accelerated atherosclerosis and arterial thrombotic events (myocardial ischemia, stroke, and peripheral artery obstructive disease), hyperglycemia and hyperlipidemia (7, 8). The risk increases with the nilotinib administration duration (9). TKIs have become the current standard of care for CML, so their cardiotoxicity should be given enough attention in this population. The mechanisms underlying the cardiovascular adverse events induced by nilotinib or imatinib remain unclear.

Nowadays, statins have been recommended for optimal atherosclerotic cardiovascular disease (ASCVD) risk reduction by American College of Cardiology/American Heart Association (ACC/AHA) Guideline (10) and European Society of Cardiology/European Atherosclerosis Society (ESC/EAS) Guideline (11). As inhibitors of 3-hydroxy 3-methylglutaryl coenzyme A reductase, statins can reduce circulating low-density lipoprotein (LDL) and cholesterol levels by 25 to 50%. Moreover, statins bring about cardiovascular benefits via anti-inflammation and atherosclerotic plaque stabilization (12). As was reported in the Network Meta-Analyses conducted by Xiaodan Zhang et al. (13), rosuvastatin ranked first in lowering low-density lipoprotein cholesterol (LDL-C), apolipoprotein B (ApoB) and increasing apolipoprotein A1 (ApoA1) efficacy. Rosuvastatin, at moderate and high intensity doses, was the most effective in reducing levels of non-high density lipoprotein cholesterol in patients with diabetes (14). Therefore, we assess the therapeutic potential of rosuvastatin and aspirin,

an important drug in prevention of ASCVD, so as to provide reference for researches on cardiotoxicity of nilotinib.

## Method

### Meta-analysis

#### Literature data sources and search strategy

This systematic review and meta-analysis were registered on the PROSPERO platform (CRD42022334398) and performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (15). The Embase, PubMed, and Cochrane Library databases were searched for articles. Moreover, we searched <https://www.isrctn.com>, <https://www.clinicaltrials.gov>, and <http://www.chictr.org.cn/index.aspx> for registered trials. The retrieval time was from inception to May 29, 2022. The detailed search strategy is described in **Supplementary Tables 1–3**.

#### Inclusion and exclusion criteria

##### Inclusion criteria

(1) Chronic myeloid leukemia patients who started with nilotinib or imatinib as first-line treatment. (2) Sufficient data and full text available for meta-analysis. (3) Study types were randomized controlled trials (RCTs) or observational studies. (4) Articles published in English.

##### Exclusion criteria

(1) Patients treated with a TKI except for imatinib or nilotinib. (2) Rotation of imatinib and nilotinib during follow-up. (3) Study types were case reports, single-cell sequencing studies, animal experiments, conference presentations, study protocols, meta-analyses or network meta-analyses.

#### Definition of the outcome

Cardiovascular adverse events (CAE), which were defined as the combination of any of the following events (1) coronary artery disease (CAD), which included but not was limited to stable angina, or acute coronary syndrome(ACS) (including unstable angina, ST or non-ST segment elevation myocardial infarction) (2) cerebrovascular accident (CVA), including stroke or transient ischemic attack (TIA) (3) peripheral artery occlusive disease(PAOD) (4) heart failure(HF) (5) pulmonary hypertension (PH) (6) arrhythmia.

#### Study selection and data extraction

Two review authors (Sicong Li and Jinshan He) independently reviewed the titles and abstracts of studies with potential eligibility. After that, we downloaded the full texts of studies eligible for inclusion. Two authors (Xinyi Zhang and Yuchun Cai) independently extracted the following data: (1) basic information, including first author, publication year,

Abbreviations: ACS, Acute coronary syndrome; BIRC3, Baculoviral IAP Repeat Containing 3; BP, biological process; CAE, Cardiovascular Adverse events; CCL2, C-C Motif Chemokine Ligand 2; CCL20, C-C Motif Chemokine Ligand 20; CC, cellular component; CVA, cerebrovascular accident; CNKI, China National Knowledge Internet; CML, chronic myeloid leukemia; ceRNA, competing endogenous RNA; CAD, coronary artery disease; CXCL2, C-X-C Motif Chemokine Ligand 2; CXCL8, C-X-C Motif Chemokine Ligand 8; DM, diabetes mellitus; DEGs, differentially expressed genes; ES, enrichment score; FDR, false discovery rate; FC, fold change; GEO, Gene Expression Omnibus database; GO, Gene Ontology; GSEA, Gene Set Enrichment Analysis; HF, heart failure; hs-CRP, high-sensitivity C-reactive protein; HTN, hypertension; IGM, impaired glucose metabolism; IL10, interleukin 10; IL6, Interleukin 6; IHD, ischemic heart disease; KEGG, Kyoto Encyclopedia of Gene and Genomes; ME, module eigengene; MM, module membership; MF, molecular function; NFKBIA, NFKB Inhibitor Alpha; NILO, Nilotinib; NES, normalized enrichment score; PAOD, peripheral artery occlusive disease; PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses; PDB, Protein Data Bank; PPI, protein-protein interaction; PH, pulmonary hypertension; RCT, randomized controlled trial; SOD2, Superoxide Dismutase 2; TIA, transient ischemic attack; TNF $\alpha$ , Tumor Necrosis Factor- $\alpha$ ; TKIs, tyrosine kinase inhibitors; VSMCs, vascular smooth muscle cells; WGCNA, weighted gene coexpression network analysis.

sample size, follow-up time and study design; (2) characteristics of patients, including sex, age and country; (3) details about the TKI treatment: dosage and duration of nilotinib or imatinib treatment; and (4) information on quality assessment. Any disagreement concerning data extraction was settled through consensus among authors.

## Strategy for meta-analysis

This meta-analysis was performed by using R (version 4.0.3). The chi-square test and  $I^2$  value were used to measure statistical heterogeneity.  $I^2 < 50\%$  and  $P > 0.05$  indicated no significant heterogeneity, and a fixed-effects model was used to pool the value of OR/HR and 95% confidence interval; otherwise, a random-effects model was used. Subgroup analysis was conducted to analyze sources of heterogeneity. Sensitivity analysis was conducted by excluding one study each time. Begg's and Egger's tests were used to assess publication bias. Statistical significance was set as  $\alpha = 0.05$  in this study.

## Quality assessment

XZ and YC assessed the quality of eligible studies independently by using the Newcastle–Ottawa Quality Assessment Scale (NOS) (16). The NOS assessed the quality of studies from the aspects of selection, comparability, and exposure, with a total score ranging from 0 to 9 points. More than 6 points was defined as a high-quality study. The results are presented in **Supplementary Table 5**.

## Bioinformatics analysis

### Data acquisition and quality control

By using “Tyrosine kinase inhibitor,” “cardiotoxicity” and “atherosclerosis” as keywords, the Gene Expression Omnibus (GEO) repository<sup>1</sup> was searched for datasets about the cardiotoxicity of nilotinib or imatinib. GSE146095 and GSE146096 with expression profiling of cardiomyocytes from *Homo sapiens* and GSE103908 with expression profiling of liver tissues from *Mus musculus* were obtained for further analysis (17). No vascular endothelial cell samples treated with TKI were found on the GEO website. We first used the *inSilicoMerging* package of R software to merge the two datasets (GSE146095 and GSE146096) (18). Then, we used the method illustrated by Johnson et al. (19) to remove the batch effect and finally obtained the transcriptomic profile matrix of human heart-derived primary cardiomyocyte-like cell lines from 16 nilotinib samples and 20 imatinib samples.

The liver plays a central role in cholesterol metabolism and lipoprotein distribution. Moreover, the liver is the main organ for the degradation of insulin, which inhibits gluconeogenesis

and promotes glycogen decomposition and the synthesis and metabolism of long-chain fatty acids and triglycerides.

In the study of GSE103908, histopathological analysis of atherosclerosis and transcriptome analysis of the liver were performed on female APOE\*3Leiden CETP transgenic mice. Sixteen of them were treated with imatinib (150 mg/kg BID), and eight of them were treated with nilotinib (10 or 30 mg/kg QD). Baseline was defined as the time point after 3 weeks on a Western-type diet containing saturated fat from 15% (w/w) cacao butter and 0.15% cholesterol. Nilotinib decreased collagen content by 32% ( $p = 0.003 < 0.05$ ) and the lesion stability index by 43% ( $p = 0.003 < 0.05$ ). Increased expression of macrophage-derived chemokine monocyte chemoattractant protein-1 (MCP-1) was observed in the nilotinib group. Imatinib reduced average cholesterol and triglyceride levels by 69% ( $p < 0.001$ ) and 36% ( $p = 0.019$ ), respectively, which was related to inhibiting VLDL production and intestinal absorption of cholesterol (20).

## Analysis of differentially expressed genes

First, the probe names were converted into gene symbol names. Second, DEGs were identified by using the “limma” package (adjusted  $p < 0.05$  and  $|\log_2\text{FoldChange}| > 1$ ). All of the DEGs were shown in a volcano plot, and the top 10 DEGs are shown in a heatmap.

## Weighted gene co-expression analysis

The WGCNA package in R software was used to find clusters of highly correlated genes (with hierarchical clustering) and to summarize these clusters as module eigengenes (MEs) by liaising with cardiotoxicity and assigning module membership (MM) to genes. After obtaining the expression profile of differentially expressed genes, we removed the genes with a standard deviation of 0 in each sample, removed the outlier genes and samples by using the *goodSamplesGenes* method in the WGCNA package, and further constructed the scale-free coexpression network. Specifically, first, Pearson's correlation matrices and the average linkage method were both performed for all pairwise genes. Then, a weighted adjacency matrix was constructed using the power function  $A_{mn} = |C_{mn}|^\beta$  ( $C_{mn}$  = Pearson's correlation between Gene *m* and Gene *n*;  $A_{mn}$  = adjacency between Gene *m* and Gene *n*).  $\beta$  was a soft-thresholding parameter that could emphasize strong correlations between genes and penalize weak correlations. After choosing the power of 20, the adjacency was transformed into a topological overlap matrix (TOM), which could measure the network connectivity of a gene defined as the sum of its adjacency with all other genes for network Gene ratio, and the corresponding dissimilarity (1-TOM) was calculated. To classify genes with similar expression profiles into gene modules, average linkage hierarchical clustering was conducted according to the TOM-based dissimilarity measure with a minimum size (gene group) of 30 for the gene dendrogram. Sensitivity was set as 2. To further analyze the module, we calculated the

<sup>1</sup> <https://www.ncbi.nlm.nih.gov/gds/>

dissimilarity of module genes, chose a cut line for the module dendrogram and merged some modules. In addition, we also combined modules with a distance less than 0.25 and finally obtained four coexpression modules. Genes in the module most related to the cardiotoxicity of nilotinib were obtained for further analysis.

### Gene ontology and kyoto encyclopedia of gene and genomes enrichment analysis

We used the DAVID website<sup>2</sup> to perform GO function and KEGG pathway enrichment analyses for genes in the most relevant module (21). Each term was calculated with a P value by using Fisher's exact test.  $P < 0.05$  was considered statistically significant. All of the results were visualized by using the bioinformatic website.<sup>3</sup>

### Construction and analysis of the protein-protein interaction network

The PPI network was constructed by using the STRING database<sup>4</sup> with a confidence score  $> 0.4$  (4). The downloaded results were imported into Cytoscape 3.8.2 (22) software for further analysis. The top 10 hub genes in the PPI network were screened out by using the cytoHubba plugin. UpsetR was used to take the intersection of the top 10 hub genes according to 5 criteria.

### Construction of the competing endogenous RNA network

miRNA-mRNA and miRNA-lncRNA interactions were obtained by searching lncACTdb (23).<sup>5</sup> In this database, we searched for ceRNA interactions supported by low- and high-throughput experiments. Finally, the ceRNA network was visualized in a Sankey plot by the R package "ggalluvial."

### Gene set enrichment analysis

We obtained GSEA software (version 3.0) from the GSEA website<sup>6</sup> (24). We downloaded the c2.cp.kegg.v7.4.symbols.gmt subset from the Molecular Signatures Database<sup>7</sup> (19) to evaluate the relevant pathways and molecular mechanisms based on gene expression profiles and phenotypic grouping. The default weighted enrichment method was used for the enrichment analysis. The random combination was set for 1000 times (25).  $|NES| > 1$ ,  $FDR < 0.25$ ,  $NOM\ p < 0.05$  were considered significant enrichment.

FIGURE 1  
Flow chart of the study selection.

### Molecular docking

Molecular docking was performed to predict the binding of rosuvastatin and aspirin to the hub proteins and the targets enriched in the atherosclerosis signaling pathway. The three-dimensional structures of rosuvastatin and aspirin were obtained from the PubChem database,<sup>8</sup> and the three-dimensional structures of hub proteins were obtained from the RCSB Protein Data Bank (PDB) database.<sup>9</sup> Molecular docking simulations between rosuvastatin, aspirin and the target proteins were performed by using the AutoDock Tool (version 1.5.6) and AutoDock Vina 1.1.2 (Molecular Graphics Laboratory, Scripps Institute, 2011). A minimum binding energy less than 5 indicated a good binding ability. The results were finally visualized by using the PyMOL molecular graphics system (v.2.4.0, Schrödinger, LLC) (26).

## Results

### Results of meta-analysis

#### Literature search

In total, 14 studies involving 9699 patients with CML were found to meet the inclusion criteria. Wang et al. (27) and Kantarjian et al. (28) reported open labeled randomized controlled studies, Anna Sicuranza et al. reported prospective cohort studies (29), while others reported retrospective cohort studies (30–40). The flow chart of the study selection process is presented in Figure 1.

## Study characteristics

The included studies were published between 2013 and 2022 and were conducted in Italy, China, Sweden, Slovakia, the USA, Germany, Japan, and Ireland. The average follow-up time ranged from 4.2 years to 10 years. Six studies did not report the dosage of nilotinib and imatinib. The relevant characteristics of the included studies are detailed in **Table 1**. Pulmonary hypertension was not included in this analysis because only one study reported it.

## Results for cardiovascular adverse events

In logistic regression and survival analysis, patients treated with nilotinib as first-line treatment suffered from a higher risk of CAE (OR 3.43 [95% CI 2.77–4.25], HR = 3.75 [95% CI 1.90, 7.40]) than those treated with imatinib (see **Figure 2**). No individual study was found to significantly influence the pooled HR and 95% CI in the sensitivity analysis. No significant publication bias was found by Begg's and Egger's tests. Torsten Dahlén (33) contributed the most to the overall heterogeneity and the overall results. In the subgroup analysis, different definitions of CAE might be the main source of heterogeneity. In terms of survival analysis, we did not construct funnel plots or perform Begg's test and Egger's test to assess publication bias due to the less than recommended arbitrary minimum number of studies.

## Results for other outcomes

Patients treated with nilotinib as first-line treatment had a higher risk of CAD (OR 5.30 [95% CI 3.85–7.29]), ACS (OR 2.7 [95% CI 1.60–4.54]), CVA (OR 5.76 [95% CI 2.84–11.28]), POAD (OR 5.57 [95% CI 3.26–9.50]) and arrhythmia (OR 2.34 [1.17,4.67]) than those treated with imatinib, while no significant difference was found in the risk of HF (OR 1.40 [95% CI 0.42–4.69]) between the two groups (**Figure 3**). The results of the publication bias assessment, sensitivity analysis and baujat plots for heterogeneity analysis are presented in **Supplementary Figures 7–10**.

Regarding the outcomes of HF and arrhythmia, we did not construct funnel plots or perform Begg's test and Egger's test to assess publication bias due to the less than recommended arbitrary minimum number of studies.

In subgroup analysis, sample size may be the source of heterogeneity in the comparison of ACS, CVA and CAD. Nilotinib treatment in studies with sample sizes greater than 1000 tended to show a higher risk of ACS, CVA and CAD than imatinib treatment. The median follow-up time, dosage and duration of nilotinib may be the source of heterogeneity in the comparison of ACS, which indicated that patients treated with more than 600 mg daily dosage or longer than 5 years of nilotinib treatment or who were followed up for more than 5 years suffered from a higher risk of ACS. In the comparison of CVA, patients treated with nilotinib tended to have a higher risk of CVA than those treated with imatinib. In studies where

FIGURE 2

Forest plots for cardiovascular adverse events (A). The results for logistic regression (B). The results for survival analysis.

patients took more than 600 mg daily dosage of nilotinib or more than 400 mg daily dosage of imatinib, the duration of imatinib or total follow-up time was more than 5 years (Supplementary Figures 1–6).

## Results of bioinformatics analysis

### Results of differentially expressed genes

In terms of human cardiomyocytes treated with nilotinib, 55 upregulated and 759 downregulated DEGs were identified through fold change (FC) and P value filtering ( $|\log_2FC| > 1$  and  $P < 0.05$ ) (see Figure 4). Interleukin 6 (IL6), C-X-C motif chemokine ligand 8 (CXCL8), C-C motif chemokine ligand 2 (CCL2), superoxide dismutase 2 (SOD2), NFKB inhibitor alpha (NFKBIA), baculoviral IAP repeat containing 3 (BIRC3), C-C motif chemokine ligand 20 (CCL20), and C-X-C motif chemokine ligand 2 (CXCL2) were upregulated in the nilotinib group, while insulin receptor substrate 1 (IRS1) was downregulated.

In liver samples of *Mus musculus* treated with nilotinib, CCL2, CXCL2, BIRC3, Transmembrane Immune Signaling Adaptor (TYROBP), and Colony Stimulating Factor 1 Receptor (CSF1R) were upregulated, while Low Density Lipoprotein Receptor (LDLR), very Low Density Lipoprotein Receptor (VLDLR), and Insulin Receptor Substrate 1 (IRS1) were downregulated compared with those treated with imatinib. TYROBP and CSF1R are important functional regulators of macrophages, which are the main inflammatory cells in vulnerable plaques and are closely related to the occurrence, development and rupture of vulnerable plaques. Decreased expression of LDLR and VLDLR in the liver can lead to hypercholesterolemia, while decreased expression of IRS1 can lead to insulin resistance (IR).

### Weighted gene coexpression network analysis

In terms of human cardiomyocyte samples, WGCNA was performed on the 814 DEGs (see Figure 5). The soft threshold for network construction was selected as 20. Meanwhile, the fitting degree of the scale-free topological model was 0.85. This

FIGURE 3

Forest plots for other outcomes. (A) Coronary artery disease (CAD). (B) Acute coronary syndrome (ACS). (C) Cerebrovascular accident (CVA). (D) Peripheral artery occlusive disease (POAD). (E) Heart failure (HF). (F) Arrhythmia.

network conformed to the power-law distribution and was closer to the real biological network state (41). Four modules were identified based on average linkage hierarchical clustering and soft-thresholding power. Among them, the magenta module showed the highest correlation with the cardiotoxicity of nilotinib (correlation index:  $0.56$ ,  $P = 3.4e^{-4} < 0.05$ ). Thirty-five genes in the magenta module were selected for further analysis.

In terms of liver samples from *Mus musculus*, the soft threshold for network construction was selected as 6. Finally, 36 modules were identified based on average linkage hierarchical clustering and soft-thresholding power. Among them, the turquoise module showed the highest correlation with atherosclerosis related to nilotinib (correlation index:  $0.77$ ,  $P = 9.7e^{-6} < 0.05$ ). A total of 182 genes in the turquoise module were selected for further analysis.

## Gene ontology and kyoto encyclopedia of gene and genomes enrichment analysis

In terms of human cardiomyocyte samples, 35 genes in the magenta module were analyzed by using the DAVID database. Thirty-two biological processes (BPs), 5 cellular components (CCs), and 8 molecular functions (MFs) were found. The top 5 results in terms of count with a significant difference ( $P < 0.05$ ) and KEGG results with a count larger than 2 are presented in the bar graph according to the P value (Figures 6A,B). The smaller the P value is, the greater the color of the bar tends to be red. The

greater the number of enriched genes, the longer the area of the bar was. The 35 genes were mainly associated with the NOD-like receptor signaling pathway, IL-17 signaling pathway, TNF signaling pathway, lipid and atherosclerosis, cytokine-cytokine receptor interaction and AGE-RAGE signaling pathway in diabetic complications.

In terms of liver samples from *Mus musculus*, genes in the turquoise module were enriched in 232 biological processes (BPs), 77-cellular components (CCs), and 8 molecular functions (MFs). In terms of KEGG analysis, genes in the turquoise module were mainly enriched in the regulation of actin cytoskeleton, chemokine signaling pathway, leukocyte transendothelial migration, PI3K-Akt, focal adhesion, Fc gamma R-mediated phagocytosis, platelet activation, natural killer cell mediated cytotoxicity, Rap1, and lipid and atherosclerosis signaling pathways (see Figures 6C,D). The results above indicated that the inflammatory response and abnormal glycolipid metabolism are the essential mechanisms in atherosclerosis related to nilotinib.

## Protein-protein interaction network analysis

The PPI network was constructed by Cytoscape based on the STRING database. In terms of human samples, the PPI network consists of 26 nodes and 54 edges (Figure 7A). The top 10 hub genes according to 5 kinds of criteria were identified by using the cytoHubba plugin (Supplementary Figure 11

Gene set enrichment analysis (GSEA) was performed to analyze the signaling pathway enrichment in the two groups.

The enrichment score (ES) and normalized enrichment score (NES) were used to indicate the analysis results across gene sets. The false discovery rate (FDR) was used to judge whether a set was significantly enriched. In human cardiomyocyte samples, no pathway was found to be significantly associated with risk scores in the nilotinib group according to the criteria ( $|NES| > 1$ ,  $FDR < 0.25$ ,  $NOM\ p < 0.05$ ).

In terms of liver samples from *Mus musculus*, 10 pathways were found to be significantly associated with risk scores in the nilotinib group, including FC epsilon RI, type II diabetes mellitus, B-cell receptor, apoptosis, insulin, natural killer cell mediated cytotoxicity, FC gamma R mediated phagocytosis, mTOR, chemokine, and T-cell receptor signaling pathways (Figure 9 and Table 3). The results indicated that nilotinib caused atherosclerosis by triggering inflammatory response and abnormal glycolipid metabolism.

### Molecular docking simulation

Rosuvastatin effectively bound to the proteins encoded by CCL20, CXCL2, NFKB1A, SOD2, BIRC3, TYROBP, and CSF1R, which were mainly enriched in the TNF and cytokine-cytokine receptor interaction signaling pathways. Aspirin could only bind

to the proteins encoded by CCL20, CXCL2, and NFKB1A, which were also enriched in the TNF signaling pathway. The molecular docking scores are presented in Table 4, while the molecular docking is visualized in Figures 10, 11. The results indicated that rosuvastatin might be effective in the treatment of atherosclerosis caused by nilotinib.

TABLE 4 Molecular docking results in terms of the minimum binding energy (kcal/mol).

Targets	Rosuvastatin	Aspirin
CCL2	−6.7	−5.3
IL6	−4.8	−4.6
CXCL8	−4.2	−2.7
CXCL2	−5.6	−5.4
NFKB1A	−6.5	−5.8
SOD2	−5.2	−0.9
BIRC3	−5.6	−4.6
TYROBP	−5.7	−4.3
CSF1R	−6.1	−4.7

## Discussion

In this meta-analysis, we conclude that patients who start with nilotinib as first-line treatment have a higher risk of CAE, CAD, ACS, CVA, POAD and arrhythmia than those with imatinib. The evidence suggests that nilotinib is not recommended for patients with advanced age, previous cardiovascular disease or high-risk factors for CAEs. It is

essential to screen for vascular risk factors, such as hypertension, hypercholesterolemia, diabetes mellitus (DM), or dyslipidemia, prior to starting nilotinib and to maintain follow-up during treatment. CML patients can be stratified according to the new Systematic Coronary Risk Evaluation (SCORE) scoring system. Patients with high and very high SCORE risk suffered from higher risk of arterial occlusive events (HR = 3.5; 95% CI = 1.4–8.7 and HR = 4.4; 95% CI = 2–9.8, respectively) (42).

**FIGURE 11**

Atherosclerosis has been considered the leading cause of CAD, ACS, CVA and POAD. Sudden rupture of vulnerable atherosclerotic plaques that are characterized by large necrotic cores, thin fibrous caps, calcification, and intraplaque hemorrhage can lead to acute cardiovascular adverse events (43). In this article, atherosclerosis caused by the inflammatory response and glycolipid metabolism disorder were considered the key mechanisms for the cardiotoxicity of nilotinib.

Nilotinib can upregulate the expression of cytokines and chemokines, such as CCL2, IL6, CXCL8, CXCL2, CXCL20, TYROBP and CSF1R, leading to a complex cascade that results in the formation and disruption of atherosclerotic plaques. Moreover, nilotinib downregulated the expression of LDLR, VLDLR and IRS1. LDLR is mainly involved in the catabolism of low-density lipoprotein (LDL), while VLDL is mainly involved in endogenous triglyceride transportation. Nilotinib can inhibit the ability of adipose tissue to store lipids, which results in the ectopic accumulation of fat and the development of insulin resistance (44, 45). Type 2 diabetes was also frequently observed in patients treated with nilotinib (8). As insulin receptors, downregulation of IRS1 can lead to insulin resistance, which can accelerate the decomposition of adipose tissue and increase the flow of free fatty acids (FFAs) into the liver (46), leading to the accumulation of diacylglycerol (DAG), activating protein kinase C (PKC), inhibiting the expression of IRS-1, and aggravating IR in the liver (47, 48). In the IR state, a high concentration of FFA can promote the activation of M1-type macrophages in the liver and promote the secretion of chemokines, such as CCL2 (MCP-1), TNF- $\alpha$ , CXCL8, CXCL2, and IL-6, which contribute to the development of atherosclerosis by regulating the activation of leukocytes, the development of foam cells and thrombosis, the proliferation of smooth muscle cells, cell egress from lesions, angiogenesis (49, 50), damage to endothelial cells and vessels (51) and the recruitment of an increasing number of monocytes and macrophages (52, 53). As a transmembrane receptor in neutrophils and monocytes/macrophages (54), TYROBP is involved in macrophage activation, lipid deposition and plaque inflammation. In the bioinformatics analysis reported by Liu et al. (55), Liu et al. (56), Zhang et al. (57), Hao and Wang (58), TYROBP was found to be one of the key Genes Involved in Advanced Atherosclerosis. CSF1R plays an important role in the survival, proliferation and differentiation of macrophages and monocytes.

However, imatinib has a positive impact on glycolipid metabolism. Imatinib can enhance the insulin-mediated vasoreactivity of resistance arteries (59), increase insulin secretion, protect against human beta-cell death (60), and reduce non-alcoholic fatty liver disease by targeting inflammatory and lipogenic pathways. Noa Markovits reported a retrospective cohort study in which long-term use of imatinib significantly reduced HbA1c (0.53%, IQR[0.09,1.19]) and FPG (10.2 mg/dL, IQR[−3.5,32.2]) in patients with diabetes, independent of demographics and glucose-lowering drug

utilization, which suggested durable metabolic benefits of imatinib (61).

As the mainstream lipid-lowering drugs, statins can block cholesterol biosynthesis in liver cells enhance the intake and clearance of LDL cholesterol (LDL-C) in blood. Moreover, statins confer cardiovascular benefits through anti-inflammatory effects (62). Rosuvastatin treatment can reduce hs-CRP and IL-6 levels in patients with coronary artery ectasia (63) and inhibit the TLR4/MyD88/NF- $\kappa$ B signaling pathway (64). In this article, rosuvastatin was found to bind to most of the hub genes and genes enriched in the lipid and atherosclerosis signaling pathways, which indicates that rosuvastatin may be effective in the treatment of CAE caused by nilotinib.

Our study had several limitations. First, the dosage was an important factor when discussing adverse drug reactions. Six studies did not report the dosage of nilotinib or imatinib, which might lead to some degree of heterogeneity. Second, some studies did not introduce the risk factors or previous history of cardiovascular events of patients included, which might lead to some degree of bias. Third, vascular endothelial cells or cardiomyocytes from CML patients treated with nilotinib or imatinib may provide more information about atherosclerosis related to nilotinib, but no dataset in this respect was found in the GEO database. Fourth, bioinformatics analysis and molecular docking can only suggest the potential mechanism and potential therapeutic drugs, which lacks experimental validation. We will conduct relevant experiments in the future.

## Conclusion

This meta-analysis suggests that patients who start with nilotinib as first-line treatment have a higher risk of cardiovascular adverse events than those with imatinib. Atherosclerosis caused by the inflammatory response and glycolipid metabolism disorders are the key mechanisms of nilotinib cardiotoxicity. Rosuvastatin may be beneficial in the treatment of CAE caused by nilotinib.

## Author contributions

XN, LS, and JL conceived of the study and design. XN conceived the early ideas for the application of the analysis models and worked on the critical revision of the manuscript. SL and JH collected data, led the analysis and interpretation of findings, and drafted the initial and subsequent versions of the manuscript. XZ and YC helped with data extraction and interpretation. All authors contributed to the analysis and interpretation of the data, revised the manuscript

for important intellectual content, and contributed to the manuscript as presented here.

## Funding

This work was supported by the National Natural Science Foundation of China to XN (Grant No. 81803497).

## Acknowledgments

We would like to thank all the scholars who have made outstanding contributions to the treatment of CML.

## Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships

that could be construed as a potential conflict of interest.

## Publisher's note

All claims expressed in this article are solely those of the authors and do not necessarily represent those of their affiliated organizations, or those of the publisher, the editors and the reviewers. Any product that may be evaluated in this article, or claim that may be made by its manufacturer, is not guaranteed or endorsed by the publisher.

**Background:** Increasing incidences of both atrial fibrillation (AF) and cancer have been observed in recent years. However, the casual association of both serious conditions has been scarcely evaluated and is considered to be a blank slate in cardio-oncology. Thus, we introduced Mendelian randomization (MR) methods to estimate the effects of AF on cancer risks.

**Methods:** We performed univariable and multivariable two-sample MR analyses to evaluate the effects of AF on the risk of 19 site-specific types of cancer. This MR study was conducted based on 111 independent AF-associated genetic instruments from genome-wide association studies and summarized-level data from corresponding cancer consortia. Multiple sensitivity analyses, including the leave-one-out analysis, MR-Egger regression, and MR-PRESSO tests, were further performed to examine the potential directional pleiotropic effects. Functional annotation was performed for common differentially expressed genes of AF and prostate cancer (PCA).

**Results:** A total of 6,777,155 European-descent people, including 533,725 cases and 6,243,430 controls, were included in the present MR analysis. Univariable MR analyses demonstrated a causal effect of AF on the incidence of PCA [odds ratio (OR): 0.96; 95% confidence interval (CI) 0.92–0.99,  $p = 0.01$ ], and the causal effect remained significant (OR: 0.65; 95% CI 0.47–0.90,  $p = 0.01$ ) after adjusting for potential confounders through the multivariable MR approach. However, no casual associations between AF and the other 18 site-specific cancer risks were observed (all  $p$ -values were  $> 0.05$ ). The consistency of outcomes across complementary sensitivity MR methods further supported the causality. The functional analysis emphasized the essential role of antioxidant and xenobiotic catabolic processes in AF and PCA.

**Conclusion:** Contrary to the findings of several previous observational studies, our comprehensive MR analyses did not corroborate a causal role for AF in increasing the risk of various types of cancer. They did, however, demonstrate that AF may decrease the risk of PCA. Studies from larger sample sizes and

individuals with different ethnic backgrounds are required to further support our conclusions.

## 1. Introduction

Atrial fibrillation (AF) is the most common cardiac arrhythmia (1) that imposes a substantial risk of death from many cardiovascular diseases and huge societal healthcare burdens. It is presumed that 6–12 million people will develop AF in the USA by 2050 and 17.9 million citizens in Europe by 2060 (2). Interestingly, a recent prospective cohort study has reported that cancer is the leading causes of death in high-income countries, accounting for two times as many deaths as cardiovascular diseases (3). Moreover, abundant evidence based on large populations shows that patients with cancer are related to an increased incidence of AF (4). However, the effect of AF on cancer risks is an uncharted field in cardio-oncology (5). Given the unacceptably high prevalence and treatment costs of both serious conditions, cardio-oncology should not be only concerned with the cardiac side effects of antineoplastic drugs in this case (6). Thus, a specific study is urgently required to find the potential associations between AF and cancer risks, which may provide new insights into the possible mechanisms and therapeutic targets.

Several observational studies have described the ambiguous effects of AF on types of cancer (7–12) due to shared risk factors and predisposing biological processes (13, 14). Prior evidence shows that patients with new-onset AF would have a noticeably increased risk of a malignant diagnosis (7), which was consistent with those of population-based cohort studies that showed that AF was related to a higher malignant incidence (8, 9, 11). However, several intrinsic methodological limitations in prior study designs may impact the observed results, thus resulting in contradictory conclusions. It is difficult, for example, for observational studies to rule out several important lifestyle differences or residual confounders (e.g., smoking, alcohol consumption, diabetes, or hypertension) in both AF and types of cancer (14). Moreover, observational results suggest that

an observed association might be attributable to instances associated with a cancer diagnosis and detection bias instead of a causal relationship (9). Consequently, there is an urgent need for a reliable study design that will assess the exact causal association between AF and cancer risks.

Mendelian randomization (MR) analysis has recently become a promising and novel epidemiological approach to assess the causal relationship between exposures and outcomes, using genetic variants as instrumental variables (IVs). Adopting genetic variants as the IVs in the MR analysis can make it less susceptible to reverse causality and hypothetical confounders. A two-sample MR analysis can be performed with robust statistical power using summary-level data from large genome-wide association studies (GWAS) (15). Hence, to solve the aforementioned issue regarding AF and types of cancer, we aimed to evaluate the causal relationship between AF and the risks of 19 site-specific types of cancer with univariable and multivariable two-sample MR methods. Given the tight association between AF and heart failure (HF) (16), we also evaluated the causality between HF and cancer risks.

## 2. Method

### 2.1. Mendelian randomization assumptions

To enable a valuable interpretation, all analyses in our MR study were based on the following three core hypotheses or study designs (17): (i) the IVs were convincingly correlated with exposures, (ii) the IVs influenced tumors only through their effects on exposures, and (iii) the IVs were independent of any confounders from the AF/HF cancer association (Figure 1A).

### 2.2. Selection of genetic instruments for exposures

The flowchart of this study is shown in Figure 1B. Exposures considered in this analysis included AF and HF. Variant AF/HF relationships were derived and manually extracted from the available summary-level GWAS. Nielsen et al. (18) carried out a GWAS with 60,620 AF cases and 970,216 controls to distinguish genetic variations. This study was mainly derived from six

Abbreviations: AF, atrial fibrillation; ANP, atrial natriuretic peptide; CIs, confidence intervals; DEG, differentially expressed gene; GWAS, genome-wide association study; GO, Gene Ontology; HF, heart failure; IVW, inverse-variance weighted; KEGG, Kyoto Encyclopedia of Genes and Genomes; LD, linkage disequilibrium; MR, Mendelian randomization; OR, odds ratio; PCA, prostate cancer; MR-PRESSO, MR Pleiotropy Residual Sum and Outlier; SNP, single-nucleotide polymorphism.

databases [deCODE, the Michigan Genomics Initiative (MGI), the Nord-Trøndelag Health Study (HUNT), UK Biobank, DiscovEHR, and the AFGen Consortium]. All enrolled patients were of European descent and generally elder people (the median age at first AF diagnosis: MGI: 65; deCODE: 74; HUNT: 76). The genetic variation of HF was derived from a GWAS meta-analysis of HF comprising 47,309 European-descent cases and 930,014 controls from the Heart Failure Molecular Epidemiology for Therapeutic Targets Consortium (19).

Given that the violation of three MR assumptions may lead to unreliable conclusions, the following steps would help choose the best IVs. First, we extracted accessible summary-level data from Nielsen et al. (18) and Sonia et al. (19) and set up a significance threshold of  $p < 5 \times 10^{-8}$ . Detailed information about AF/HF-related single-nucleotide polymorphisms (SNPs) is shown in [Supplementary Table 1](#). To measure genetic correlation, we further conducted a linkage disequilibrium (LD) clumping test at an  $R^2 < 0.001$  and

10,000 kb window to preserve the SNPs that were most robustly associated with the AF/HF for downstream analysis. To exclude bias from weak instruments, the  $F$ -statistic value was assessed on the bias of the formula  $F = \frac{R^2(N-k-1)}{k(1-R^2)}$ , where  $R^2$  is the proportion of variance explained by the IVs,  $k$  and  $N$  are the number of SNPs and enrolled patients, respectively.  $F$ -statistic values  $> 10$  were robust enough to avoid weak instrument bias. Eventually, several SNPs were excluded to eradicate the genetic bias created by palindromes with intermediate allele frequencies (20), and we created a total of 111 and 12 SNPs as the original AF- and HF-IVs, respectively.

### 2.3. Study participants of various types of cancer

To obtain genetic data for 19 site-specific tumors, we analyzed the following European cancer consortia: Breast Cancer Association Consortium (BCAC) (21) (breast cancer: 122,977 patients and 105,974 controls; ER-positive breast cancer: 69,501 patients and 105,974 controls; and ER-negative breast cancer: 21,468 patients and 105,974 controls), Prostate Cancer Association Group to Investigate Cancer Associated Alterations in the Genome (PRACTICAL) (22) [prostate cancer (PCA): 79,148 patients and 61,106 controls], International Lung Cancer Consortium (ILCCO) (23) (lung cancer: 11,348 patients and 15,861 controls, lung adenocarcinoma: 3,442 patients and 14,895 controls; and squamous cell cancer: 3,275 patients and 15,038 controls), PanScan1 (24) (pancreatic cancer: 1,896 patients, 1,939 controls), GliomaScan (25) (glioma: 6,811 patients, 1,856 controls), the Medical Research Council-Integrative Epidemiology Unit (MRC-IEU) consortium (kidney cancer: 1,114 patients, 461,896 controls; pancreatic cancer: 1,114 patients, 461,896 controls; rectum cancer: 1,470 patients, 461,540 controls), Neale lab (colon cancer: 2,437 patients, 358,757 controls; lymphoma: 1,752 patients, 359,442 controls; melanoma: 3,598 patients, 459,335 controls), and other databases (malignant neoplasm of bone and articular cartilage: 119 patients, 174,006 controls; thyroid cancer: 989 patients, 174,006 controls; bladder cancer: 1,279 patients, 372,016 controls; mesothelioma: 133 patients, 174,006 controls; meningiomas: 455 patients, 86,713 controls) (Table 1).

### 2.4. Statistical analysis of MR estimates

All MR analyses were performed in R 4.0.5 using the package TwoSampleMR (version 0.5.0).

#### 2.4.1. Two-sample MR method

We performed the inverse-variance weighted (IVW) test, which can provide a coherent estimation of the causality

between genetically determined exposures and outcomes. It is made up of a meta-analysis of a single SNP's Wald ratio between the exposures and outcomes using a random-effects inverse-variance method, which can weigh every single Wald ratio according to its standard error to judge potential measurable heterogeneity (20). The causal effects were calculated and presented in the form of odds ratios (ORs) with 95% confidence intervals (CIs) for 14 site-specific types of cancer. Two-sided  $p$ -values  $< 0.05$  were considered to be statistically significant. Of note, the results of IVW tests might be biased given the horizontal pleiotropy in invalid instrumental variables. Hence, the MR-Egger regression and the weighted-median estimate were conducted to predominantly assess the MR outcomes (20, 26). The MR-Egger regression can amend the IVW test by allowing a nonzero intercept that can provide an exploration of pleiotropy and an evaluation of the causality adjusted for pleiotropy (20). The weighted-median analysis is used to pool the median effects of all SNPs and can return an unbiased estimate once 50% of the SNPs are valid instruments (20). Finally, the MR Pleiotropy Residual Sum and Outlier (MR-PRESSO) test was conducted using the "MRPRESSO" R package to distinguish outlying SNPs that may result in horizontal pleiotropy and causal effects.

#### 2.4.2. Multivariable MR analysis

To support the univariate MR results and the third assumption, multivariable MR analyses adjusted for confounders, including smoking (trait ID: ukb-a-225), alcohol consumption (trait ID: ukb-d-20117\_2), type 2 diabetes (trait ID: ebi-a-GCST006867), and hypertension (trait ID: ukb-b-14057) were introduced. Multivariable MR showed that the SNPs used in univariate MR analyses were also related to these confounders. Then, multivariable MR estimated the effects of each exposure on a single outcome. That is, this can simultaneously assess the effects of all risk factors that share a set of overlapping SNPs and make sure that the direct effects of each exposure on outcomes will not be mediated by other factors (27). As we included MR analyses of 19 site-specific types of cancer, a Bonferroni-adjusted  $p$ -value less than the threshold (i.e.,  $0.05/19 = 0.0026$ ) was deemed as a significant causality to adjust for multiple-comparison tests. A potential relationship was considered significant if a  $p$ -value is between 0.05 and 0.0026.

### 2.5. Pleiotropy and sensitivity analysis

We conducted the leave-one-out analyses to assess whether the results of the IVW tests would be biased by single-sensitive SNPs (26). The aforementioned Egger intercept analysis was then performed to estimate the horizontal pleiotropy. The MR-heterogeneity analysis was ultimately performed to single

out SNPs that were responsible for heterogeneity in causal estimation by means of Cochran's Q-test (28).

## 2.6. Identification and enrichment analyses of DEGs

Two PCA-related microarray datasets [GSE46602 (29) and GSE70768 (30)] and one AF-related dataset [GSE41177 (31)] were downloaded from the GEO (<http://www.ncbi.nlm.nih.gov/geo>) database to select differentially expressed genes (DEGs). Herein, genes with an adjusted  $p$ -value of  $< 0.05$  and  $|\log FC| \geq 1$  were considered DEGs. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway were performed to explore the potential biological functions of DEGs.

## 3. Results

In general, this MR study included a total of 6,334,916 European-descent people, with 463,502 cases and 5,871,414 controls (Table 1). Considering the variation in sample sizes of different cancers,  $F$ -statistics values in this study ranged from 273.8 to 369.1. The instruments ( $F > 100$ ) used in our MR analyses were very strong to avoid bias (Table 1). All the MR evaluations for multi-polymorphism scores are shown in Tables 2, 3. Our results indicated that the genetically predicted AF was associated with a decreased risk of cancers of PCA and found no detrimental effects of AF/HF on the other 18 site-specific cancer risks (Tables 2, 3). The estimated effect sizes of the SNPs on both exposure (AF) and outcomes (PCA, breast cancer, lung cancer, and kidney cancer) are displayed in scatterplots (Figure 2).

### 3.1. Association of genetic liability to exposures with cancer risks

#### 3.1.1. Univariable MR results

The results of the IVW test revealed a suggestive association of genetic liability to AF and PCA (OR = 0.96; 95% CI 0.92–0.99,  $p = 0.01$ ) (Table 2). However, no relationships of genetic liability to AF with lower odds of breast cancer (OR = 1.003; 95% CI 0.97–1.035,  $p = 0.87$ ), ER-negative breast cancer (OR = 1.009; 95% CI 0.96–1.06,  $p = 0.7$ ), ER-positive breast cancer (OR = 0.99; 95% CI 0.96–1.03,  $p = 0.76$ ), lung cancer (OR = 1.00; 95% CI 0.94–1.06,  $p = 0.97$ ), lung adenocarcinoma (AF: OR = 1.01; 95% CI 0.93–1.10,  $p = 0.76$ ), and squamous cell lung cancer (OR = 1.004; 95% CI 0.92–1.10,  $p = 0.93$ ) were observed. Regarding other 12 site-specific types of cancer, limited evidence validated a causal association of genetic liability to AF with the risk of kidney cancer (OR = 1.0001; 95% CI 0.9996–1.0006,  $p = 0.71$ ), melanoma (OR = 1.0003; 95% CI

0.9999–1.0011,  $p = 0.93$ ), lymphoma (OR = 1.00016; 95% CI 0.995–1.00049,  $p = 0.95$ ), glioma (OR = 1.15; 95% CI 0.97–1.36,  $p = 0.12$ ), colon cancer (OR = 0.9998; 95% CI 0.9992–1.0004,  $p = 0.44$ ), rectum cancer (OR = 1.0002; 95% CI 0.9997–1.00068,  $p = 0.27$ ), meningiomas (OR = 0.95; 95% CI 0.76–1.18,  $p = 0.65$ ), thyroid cancer (OR = 0.95; 95% CI 0.84–1.09,  $p = 0.48$ ), and bladder cancer (OR = 0.9999; 95% CI 0.9996–1.00038,  $p = 0.9$ ); malignant neoplasm of bone and articular cartilage (OR = 0.78; 95% CI 0.54–1.13,  $p = 0.2$ ); and mesothelioma (OR = 1.24; 95% CI 0.85–1.81,  $p = 0.27$ ) (Table 2). Some outliers were observed with the MR-PRESSO analysis, and the results remained in line with the original ones after removing these outliers (Supplementary Table 2). Additionally, we also found no associations between HF and 19 site-specific cancer risks (Table 3).

#### 3.1.2. Multivariable MR analysis

As illustrated in Figure 3 and Supplementary Table 3, after adjusting for potential pleiotropic or mediating effects, multivariable MR still expounded strong independent associations between genetic predisposition to AF and PCA (OR = 0.94; 95% CI 0.90–0.98,  $p = 0.0048$ ) and yielded similar results that AF was not associated with the increased risk of other site-specific cancer types.

### 3.2. Assessment of MR assumptions

The first assumption was met because our included SNPs were selected at the genome-wide significance threshold of  $p < 5 \times 10^{-8}$  and  $F$ -statistics values ranged from 273.8 to 369.1 ( $F > 100$ ). Leave-one-out analysis suggested that individual SNPs had no impact on the overall effect of AF on cancer risks. Moreover, the MR-Egger regression analysis suggested that the impact of pleiotropy was negligible because intercepts were not statistically significant (all  $p$ -values  $> 0.05$ ) (Supplementary Table 4). Sensitive analyses demonstrated that the second MR assumption was not violated. Although the Cochran Q-tests showed certain horizontal pleiotropy, little influence affected the overall results because no pleiotropy biased the results of the MR-Egger and MR-PRESSO tests (32). With regard to the third MR assumption, multivariable MR and MR-PRESSO analyses eliminated pleiotropic effects, which abided by the third MR assumption.

### 3.3. Analysis of the functional characteristics of common DEGs

In total, 51 common DEGs between AF-related and PCA-related datasets were identified (Figure 4A). Results of the KEGG pathway demonstrated that several significant

TABLE 2 Mendelian randomization estimates of the casual relationships between atrial fibrillation and cancer risks.

Exposure	nSNPs	IVW method		Weighted median method		MR-Egger

**FIGURE 2**  
Scatterplots for MR analyses of the causal effect of atrial fibrillation on cancer risks: **(A)** prostate cancer; **(B)** breast cancer; **(C)** lung cancer; and **(D)** kidney cancer. The x-axis represents the previously published  $\beta$ -estimate for the association of each SNP with atrial fibrillation. The y-axis outlines the  $\beta$ -estimate for the relationship of each SNP with cancer risks by means of the multivariate logistic regression model. Lines represent causal estimates from the different methods. The slope of each line indicates the estimated MR effect per method. Circles correspond to marginal genetic associations with atrial fibrillation and risk of outcome for each variant. Error bars indicate 95% confidence intervals. SD, standard error; MR, Mendelian randomization.

enrichment pathways were noted, such as glutathione metabolism and metabolism of xenobiotics by cytochrome P450 (all  $p$ -values were  $<0.05$ ) (Figure 4B). Regarding GO analysis, these DEGs were mainly enriched in cellular detoxification, xenobiotic metabolic process, glutathione derivative metabolic process, cellular response to xenobiotic stimulus, glutathione binding, and antioxidant activity (all  $p$ -values were  $<0.05$ ) (Figures 4C, D). These outcomes firmly revealed that the antioxidant activity, xenobiotic catabolic

process, and cytochrome P450 metabolism were involved in the development of AF and PCA.

## 4. Discussion

### 4.1. Principal findings

In this study, we performed MR analyses to evaluate whether genetic evidence supported a causal association between AF and

FIGURE 3

Multivariable Mendelian randomization analyses adjusted for smoking, alcohol consumption, diabetes, and hypertension. \*Means statistically significance.

the risk of 19 site-specific types of cancer. To the best of our knowledge, this is the first cardio-oncology MR study involving 6,334,916 people to explicate that AF may casually reduce the risk of PCA. Moreover, little evidence demonstrated that AF and closely related HF were casually related to the increased risks of lung cancer, breast cancer, PCA, kidney cancer, glioma, pancreatic cancer, colon cancer, rectum cancer, meningiomas, thyroid cancer, bladder cancer, lymphoma, or melanoma, with less susceptibility to potential confounders and inverse causation. Based on our findings, cancer screening beyond standard routine healthcare may not be currently merited with a new diagnosis of AF. Nonetheless, a tight collaboration between cardiologists and oncologists is still essential to improve the management of patients, which may provide crucial mechanistic and therapeutic insights with regard to both serious conditions.

## 4.2. Previous research

The present MR findings do not support previous observational studies, suggesting that the manifestation of AF was a marker of occult cancer. Several sporadic epidemiological trials have described the underlying effect of AF on site-specific malignancies, but their findings were very controversial. An observational cohort study by Conen et al. (12) included 34,691

women and revealed that women with new-onset AF may have an elevated cancer risk beyond 1 year of AF diagnosis. This questionnaire-derived study also indicated that new-onset AF was statistically significant for the risk of colon cancer, whereas significant multivariable-adjusted relationships for breast cancer were not observed (12). These findings were consistent with a Danish population-based cohort study enrolling 26,222 men and 28,879 women free of AF (8). In this cohort trial, AF was not related to breast cancer or PCA (8), but the risk of colorectal cancer and lung cancer was paradoxically remarkably high within the initial 90 days following the diagnosis of AF (8). A retrospective cohort of 5,130 patients, however, demonstrated that the standard incidence ratio of lung and colon cancer was significantly high in patients with AF, although there was no significant increase in the risks of liver or breast cancer (11). Interestingly, evidence from a prospective cohort study even reached a contrasting conclusion that AF was related to decreased odds of the new diagnosis of breast cancer and colorectal cancer, indicating that an association noted in a previous study may be caused by potential detection bias instead of a causal relationship (9).

Atrial fibrillation and HF are often presented together with each other (16), and a similar scenario also holds for the relationship between HF and cancer risks. Retrospective research has suggested that the prevalence of malignancy in

FIGURE 4

(A) Venn diagram showed an overlap of 51 DEGs. (B) The enrichment analysis results of KEGG Pathway. (C, D) The enrichment analysis results of GO terms.

established HF ranges from 18.9 to 33.7 per 1,000 person-years (33–35). Conversely, a study with larger cohorts and longer follow-up durations explicated that HF was neither associated with an increased risk of cancer nor cancer-specific deaths (36). Overall, according to previous studies, an association between AF and malignant tumors has been reported but is largely controversial.

### 4.3. The interpretation of the observed results

The potential limitations in previous epidemiological studies may bias the observed outcomes. The conflicting outcomes

regarding cancer risks and AF in prior studies may be mediated by lots of possibilities, and some of the potential relationships are complex.

First, it was not surprising to see elevated cancer risks in patients with AF because related treatments render clinically overt cancer that could be otherwise asymptomatic. Several cardiovascular drugs, including spironolactone (37) and aspirin (38), have been shown to lower the carcinogenesis of certain types of cancer. In addition to the effect of related treatments, inherent drawbacks in observational study design, such as shorter follow-up duration, possible selection/surveillance bias (8, 12), and a lack of comprehensive data on shared risk factors (14, 39), could explain the perplexing results. The median time from AF/HF to malignancy diagnosis in some

prior investigations was <3 years (33, 35), which might be too short of a period to expound a causal association. With regard to selection or surveillance bias, some questionnaire-based studies may be unable to accurately determine whether patients underwent the examination before or after AF diagnosis (12). Besides, patients with screen-detected AF are more possible to have cancer screenings at an early stage, which is usually missed in the general population. For instance, if silent malignancies stay undetected, AF-related antithrombotic (40) or anticoagulant agents (8, 12) could increase the positivity rate of intestinal hemorrhage or hematuria, thus followed by several cancer detections (41). Third, AF and cancer are complex conditions and share many common risk factors, including alcohol consumption, smoking, hypertension, and diabetes (42). The risk of malignancy in patients with AF will naturally increase with the presence of the number of these risk factors. Hence, minimizing the effects of confounders and limitations of study designs is necessary for the evaluation of causality.

#### 4.4. Possible mechanisms

In the present MR analysis, we found that AF may lower the risk of PCA using univariable and multivariable MR methods. The observed findings may be first attributed to an atrial natriuretic peptide (ANP), which may provide meaningful information about the underlying mechanism. AF is an independent determinant of ANP that exerts an important role in restraining tumor growth (43, 44). The inhibition of malignant cell proliferation by ANP is mediated by both intracellular acidity and Wnt/ $\beta$ -catenin signaling (45). ANP might also hinder the adhesion of malignant cells to microvascular endothelial cells by suppressing the E-selectin expression, which is regulated by inflammation (46). Second, AF-related hypercoagulability would alter cancer cell adhesion and tumor progression by decreasing matrix metalloproteinases (MMPs) in tissue and increasing circulating levels of inhibitors of matrix metalloproteinases (TIMPs) (5). TIMPs could control MMP that could lead to the degradation of the extracellular matrix and, consequently, organize the path for malignant cells to progress and spread to distant secondary areas (47). Third, certain immune-related genes identified in AF have recently been linked to the prognosis and immune infiltration in several tumor types (48). Herein, present KEGG and GO enrichment analyses of 51 common DEGs also revealed that these genes were significantly enriched in antioxidant activity, xenobiotic catabolic processes, and cytochrome P450 metabolism pathways. It has been expounded that the cause of PCA occurrence might be the outcome of an imbalance of antioxidants (49). Antioxidant defenses might be notably attenuated in patients with PCA (50). Moreover, environmental xenobiotics are largely involved in PCA development and are metabolized by cytochrome P450 in the human organism (51).

#### 4.5. Strengths and limitations

The present MR study has several notable strengths. First, this is the first MR study conducted to evaluate the causal association between AF and cancer risks. MR analysis is deemed a reliable epidemiological method to evaluate the causality between exposures and outcomes. Residual confounding from unmeasured variations of baseline information may not ascertain cause-effect associations in previous studies (7, 8, 11, 12). The MR analysis, however, may better diminish the interference of confounders and inverse causation. Moreover, we were more likely to portray a relatively independent causal inference from AF to cancer risks with the multivariable MR approach adjusted for confounders. Second, the included AF-associated SNPs as IVs were gained from all documented GWASs, which may better explicate the variation of AF. Third, the present genetic summary data of certain types of cancer were obtained from large-scale consortia (namely, ILCCO, BCAC, and PRACTICAL), including millions of cases, which were far more than some previous studies (7, 11, 12). Compared with the low-occurrence rates of certain tumors in the previous studies (7, 11, 12), the present results from a relatively large sample size and strongly related IVs could present sufficient statistical power and a precise assessment of causal effects.

Some drawbacks should be taken into account to better elucidate the present findings. The participants in our study were of European descent. Thus, the results of our analysis were less likely to be biased by population stratification, but whether our assertion could be generalizable to other populations for different genetic backgrounds needs to be verified. Besides, the sample size of several site-specific cancer types in our analysis was small. For example, the consortium of malignant plasma cell neoplasms consisted of only 180 patients compared with its vast number of 87,061 controls. The statistical power may not estimate their causality accurately. Finally, the association between AF and PCA was not maintained in the results of MR weighted-median and MR-Egger analyses. However, the direction of MR estimates was consistent among IVW, weighted median, and MR-Egger methods in this study. Moreover, MR-PRESSO and multivariable MR tests were conducted to distinguish possible horizontal pleiotropy and supported the original IVW results.

#### 5. Conclusion

This large cardio-oncology study revealed that AF may reduce the risk of PCA. Despite the lack of a causal relationship between AF and increased cancer risks, we should not ignore the two diseases' shared risk factors and pathophysiological mechanisms. Numerous studies still investigate the complicated interrelations between AF and cancer stay and, with an aging population, it

represents a valuable field for future investigation. A multidisciplinary approach is still needed to better understand the underlying mechanisms regarding the links between AF and cancer risks.

## Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/[Supplementary material](#).

## Ethics statement

Ethical review and approval was not required for the study on human participants. Written informed consent was not required to participate in this study.

## Author contributions

WL, MH, and WW conceived and designed the study, collected, analyzed, and interpreted the data. The first version of the manuscript was written by WL, RW, and WW. All authors contributed to the article and approved the submitted version.

## Funding

This study was supported by the National Natural Science Foundation of China Grants (81172243 and 81572966 to WW)

**Background:** Breakpoint cluster region-Abelson gene (BCR-ABL) tyrosine kinase inhibitors (TKIs) have revolutionized the treatment of patients with chronic myeloid leukemia (CML). However, concern has arisen about the cardiac safety profile of these drugs.

**Objectives:** This study aims to compare long-term risks of adverse cardiovascular and cerebrovascular events (ACE), heart failure or left ventricular ejection fraction (LVEF) < 50%, and venous thromboembolic events (VTE) in patients with CML treated with BCR-ABL TKIs, using data from a large multinational network.

**Methods:** Patients aged  $\geq 18$  years with CML treated with imatinib, dasatinib, or nilotinib without prior cardiovascular or cerebrovascular disease were included. We used propensity score matching to balance the cohorts. The 5-year cumulative incidences and hazard ratios were calculated.

**Results:** We identified 3,722 patients with CML under treatment with imatinib ( $n = 1,906$ ), dasatinib ( $n = 1,269$ ), and nilotinib ( $n = 547$ ). Patients with imatinib compared to dasatinib showed a higher hazard ratio (HR) for ACE (HR 2.13, 95% CI 1.15–3.94,  $p = 0.016$ ). Patients with imatinib presented a lower HR than nilotinib for ACE (HR 0.50, 95% CI 0.30–0.83,  $p = 0.0074$ ). In relation to heart failure or LVEF < 50%, patients with imatinib had a higher HR than dasatinib (HR 9.41, 95% CI 1.22–72.17,  $p = 0.03$ ), but no significant difference was observed between imatinib and nilotinib (HR 0.48, 95% CI 0.215–1.01,  $p = 0.064$ ).

**Conclusion:** In this retrospective study with a large number of patients with CML, those treated with nilotinib had a higher 5-year ratio of ACE, while patients with dasatinib showed a lower ratio than patients with imatinib. The ratio of heart failure was higher in patients with imatinib than in patients with dasatinib, but not when compared to nilotinib.

#### KEYWORDS

cardiovascular safety, chronic myeloid leukemia, tyrosine kinase inhibitor (TKI), breakpoint cluster region-abelson (BCR-ABL), cardio-onco-hematology

## Introduction

Chronic myeloid leukemia (CML) is a myeloproliferative disorder caused by a balanced chromosomal translocation involving a fusion of the Abelson gene (ABL1) from chromosome 9q34 with the breakpoint cluster region (BCR) gene on chromosome 22q11, known as the Philadelphia chromosome, which encodes the BCR-ABL protein with protein tyrosine kinase activity (1). The advent of BCR-ABL tyrosine kinase inhibitors (TKI) was a big breakthrough in the treatment of patients with CML, improving their outcomes and quality of life. In 2001, imatinib was the first BCR-ABL TKI approved for the treatment of patients with CML (2). Posteriorly, other BCR-ABL TKIs such as dasatinib and nilotinib were also approved for this purpose.

Despite their well-known benefits for CML treatment, concerns have been raised about short- and long-term cardiac and pulmonary safety profiles of BCR-ABL TKIs. Cardiac toxicities associated with TKIs are heterogeneous and may include QT prolongation, arrhythmias, decreased left ventricular ejection fraction (LVEF), congestive heart failure, acute coronary syndrome, arterial thrombosis, pulmonary, and systemic hypertension (3–10). TKI-induced cardiotoxicity mechanisms are miscellaneous and may be drug-specific, even to same-class drugs. Proposed mechanisms may include disruption of mitochondrial function within the cardiomyocyte, off-target inhibition of other kinases, disturbing cardiomyocyte cellular oxidative phosphorylation, and caspase-mediated mitochondrial apoptosis (11).

Despite data from clinical trials and cohort studies, there is still a need for more robust information about the long-term cardiac safety profile of BCR-ABL TKIs, especially real-world data. Trials evaluating BCR-ABL TKIs in patients with CML have enrolled participants with a history of cardiovascular disease but, when cardiac endpoints were reported, these patients were not analyzed as a separate group (12). Also, the definition of cardiovascular outcomes in TKI studies was heterogeneous and generally, they were not the same as those of cardiologic trials as well as they were not specifically designed to determine cardiac safety.

Based on the previous literature data, we hypothesized that cardiovascular outcomes may differ according to the treatment with specific BCR-ABL TKIs. In this study, we aimed to evaluate the 5-year incidence and compare the ratios of significant cardiovascular outcomes in patients with CML without a past history of heart or cerebrovascular diseases treated with Bcr-ABL TKIs imatinib, dasatinib, or nilotinib, using data from a large multinational network based on electronic medical records.

## Materials and methods

### Data source

We used global-based data from the network TriNetX (TriNetX, Inc., Cambridge, MA, United States), a multinational collaborative clinical research platform, that collects real-time medical records, including demographics, diagnoses, procedures, medications, laboratory values, and vital statuses. This network included 70 healthcare organizations at the time of analysis, including data from around 69.8 million patients. The TriNetX platform uses aggregated counts and statistical summaries of de-identified information so that no protected health information or personal data are made available to users of the platform. Data were extracted and analyzed from the Global Collaborative Network on the TriNetX platform between 27 August and 30 August 2021.

### Study population

We queried the databank to select patients of both sexes and with age  $\geq 18$  years with CML, BCR-ABL positive, based on International Classification of Diseases, Tenth Revision (ICD-10) diagnosis codes (ICD-10 code C92.1) during the past 10 years before the analysis. The patients needed to be under treatment with a BCR-ABL TKI (imatinib, dasatinib, or nilotinib), and they must not be prescribed another TKI anytime. The index date was determined by the earliest date of identification of the use of a BCR-ABL TKI. Patients with past ischemic heart disease, other forms of heart disease (including patients with LVEF  $< 50\%$  identified in the TriNetX databank), cerebrovascular disease, and pulmonary hypertension (ICD-10 codes I20-I25, I27, I30-I52, and I60-I69) before the index date were excluded from the analysis.

### Study design

In this population-based retrospective cohort study, we aimed to analyze the 5-year incidence of cardiovascular outcomes [adverse cardiovascular and cerebrovascular events (ACE), heart failure or LVEF  $< 50\%$ , and venous thromboembolic events (VTE)] and their comparative hazard ratios (HR) in patients with CML BCR-ABL positive under treatment with imatinib, dasatinib, or nilotinib. The time window for the outcome was the treatment starting with a BCR-ABL TKI up to 5 years after. To avoid interactions in

cardiovascular outcomes from patients with CML that were changed from one TKI to another, patients with switch therapy were excluded from the analysis.

## Outcomes

The three analyzed cardiovascular outcomes are as follows:

**Adverse cardiovascular and cerebrovascular events (ACE):** the composite of ischemic heart disease (ICD-10 codes I20–I25) or cerebrovascular disease (ICD-10 codes I60–69) or myocardial revascularization (coronary angioplasty code or coronary artery bypass graft surgery, ICD-10 codes Z95.1, Z95.5, and Z98.61).

**Heart failure or left ventricular ejection fraction (LVEF) < 50%:** ICD-10 code I50 or TriNetX code 2003. LVEF < 50% was chosen as a surrogate for ventricular dysfunction.

**Venous thromboembolism (VTE):** ICD-10 I82 or I26.

## Statistical analysis

The baseline characteristics for each group were compared with the chi-square test for categorical variables and the Student *t*-test for continuous variables. Propensity score matching was used to balance cohorts with baseline characteristics. In relation to outcome comparisons, we used the imatinib group as the reference, comparing it with the two other groups (dasatinib and nilotinib). Kaplan–Meier analysis was performed to estimate the probability of outcomes after the index date from 1 day up to 5 years. Comparisons between cohorts were made using a log-rank test. We calculate the HRs and their associated 95% confidence intervals (CI), together with the test for proportionality based on the scaled Schoenfeld residual, using R's Survival package v3.2-3.

Statistical analyses were done within TriNetX (13). Statistical significance was set at a two-sided *p*-value of < 0.05.

## Propensity score matching and covariates

The propensity score matching was calculated using logistic regression implemented by the function logistic regression of the scikit-learn package in Python version 3.7. “Greedy nearest neighbor matching” was used with a caliper of 0.1 pooled standard deviations (13). 1:1 matching was adjusted for covariates that could be confounders for the predefined cardiovascular outcomes as follows: demographic variables such as age, sex, and race (defined as white, black or African American, Asian, or unknown); health conditions related to cardiovascular risk and recorded identified from ICD-10-CM codes in electronic medical records: overweight or obesity, hypertension, chronic kidney disease, dyslipidemia, diabetes mellitus, and nicotine dependence; and use of cardiovascular and antimetabolite medications: hydroxyurea, diuretics, ACE inhibitors or angiotensin II receptor blockers, beta-blockers, lipid-lowering drugs, and antiarrhythmics, before starting BCR-ABL TKIs.

## Ethics

TriNetX-derived studies with de-identified information were approved by the Institutional Review Board of Hospital Alemão Oswaldo Cruz.

## Results

### Characteristics of the study population

Using the electronic medical records from the platform TriNetX, we identified 24,921 patients with CML BCR/ABL positive (ICD-10 C92.1). From this cohort, we selected, using inclusion and exclusion criteria, 3,722 patients with CML and without past heart disease treated with imatinib (*n* = 1,906), dasatinib (*n* = 1,269), and nilotinib (*n* = 547). The exposure time for each analyzed TKI was as follows: imatinib (median 1,198 days, range 1–1,826 days), dasatinib (median 647 days, range 1–1,826 days), and nilotinib (median 790 days, range 1–1,826 days).

Compared to imatinib, patients with dasatinib were younger during the start of treatment with a TKI (age 55 vs. 47.7 years old, *p* < 0.0001), had a lower rate of hypertension (21 vs. 16%, *p* < 0.0001), and had diabetes mellitus (10 vs. 7%, *p* = 0.002). The patients with dasatinib had a higher rate of previous treatment with hydroxyurea (*p* < 0.0001) and antiarrhythmics (*p* < 0.0001) than patients in the imatinib group.

Compared to the imatinib group, patients from the nilotinib group were younger (55 vs. 53 years old, *p* = 0.008), had a higher proportion of female patients (46 vs. 52%, *p* = 0.007), and had a higher proportion of black or African American patients (11 vs. 15%, *p* = 0.02). Patients with nilotinib had a lower rate of use of antiarrhythmics than patients with imatinib. The baseline characteristics before propensity score matching of the three study groups are detailed in **Table 1**.

### Outcome incidences during 5-year follow-up before the propensity score matching

The number and cumulative incidence of patients with ACE in the Imatinib group were 99 (5.23%), in the dasatinib group were 15 (1.19%), and in the nilotinib group were 44 (8.1%). For the composite outcome heart failure or LVEF < 50%, the number and cumulative incidence in the imatinib group were 35 (1.83%), in the dasatinib group were 10 (0.78%), and in the nilotinib group were 17 (3.1%). The composite outcome VTE or pulmonary embolism occurred in 45 (2.4%) patients in the imatinib group, 25 (2%) patients in the dasatinib group, and 10 (1.8%) patients in the nilotinib group.

### 5-year outcomes in imatinib, dasatinib, and nilotinib groups after propensity score matching

After the propensity score matching, the imatinib group (*n* = 1,153) compared to the dasatinib group (*n* = 1,153) showed a

higher HR for ACE (HR 2.13, 95% CI 1.15–3.94,  $p = 0.016$ ). When compared with the nilotinib group ( $n = 533$ ), the matched imatinib group ( $n = 533$ ) presented a lower HR for ACE (HR 0.50, 95% CI 0.30–0.83,  $p = 0.0074$ ). In relation to heart failure or LVEF < 50%, patients with imatinib had a higher ratio than patients with dasatinib (HR 9.41, 95% CI 1.22–72.17,  $p = 0.03$ ), but no significant difference was observed between imatinib and nilotinib groups (HR 0.48, 95% CI 0.215–1.01,  $p = 0.064$ ). There were no significant differences between the three groups in relation to VTE or pulmonary embolism. Five-year Kaplan–Meier curves for ACE, heart failure, and venous thromboembolism between dasatinib vs. imatinib and nilotinib vs. imatinib are depicted in **Figure 1**.

## Discussion

We used a large electronic medical record network to create propensity score-matched cohorts of patients with CML without a past history of heart or cerebrovascular diseases according to the treatment with three commonly used BCR-ABL TKIs for comparing ratios of cardiovascular outcomes (ACE, heart failure or LVEF < 50%, and VTE or pulmonary embolism) during a 5-year period. As

patients of the imatinib group were older than patients of the other groups and had more cardiovascular risk factors than patients of the dasatinib group, we opted for matching the cohorts as a reasonable approach to compare the groups with similar baseline characteristics for reducing bias. Using this approach, we found that when compared with patients from the imatinib group, patients with dasatinib had a significantly lower ratio of ACE, while patients from the nilotinib group had a significantly higher rate of ACE.

Cardiovascular events, including ischemic heart disease, cerebrovascular disease, and peripheral artery disease, are major concerns in patients with CML, particularly in those under treatment with second- and third-generation Bcr-ABL TKIs nilotinib and ponatinib, respectively (14). In this population, cardiovascular disease may be responsible for up to 16.5 and 5% of potential years of life lost in men and women, respectively (15). In the 3-year follow-up of the ENESTnd trial, which included a total of 846 patients with newly diagnosed Ph + CML-CP, the incidence of ischemic heart disease was higher with nilotinib than with imatinib: nine patients (3.2%) in the nilotinib 300 mg twice-daily arm, 11 patients (4.0%) in the nilotinib 400 mg twice-daily arm, and three patients (1.1%) in imatinib arm (9). These results were more evident with a 5-year update of the ENESTnd trial, in which 28 of 279 (10%) patients

FIGURE 1

5-year Kaplan-Meier curves for adverse cardiovascular or cerebrovascular events, heart failure or LVEF < 50%, and VTE or pulmonary embolism in patients treated with imatinib vs. dasatinib (left column) and imatinib vs. nilotinib (right column). LVEF, left ventricular ejection fraction; HR, hazard ratio; CI, confidence interval; VTE, venous thromboembolism.

treated with nilotinib at 300 mg twice per day, 44 of 277 patients (15.9%) treated with nilotinib at 400 mg twice per day, and 7 (2.5%) of 280 patients treated with imatinib 400 once per day had ischemic events (16). Interestingly, a retrospective study using data from 1,390 patients with CML from IRIS, TOPS, and ENESTnd trials showed a lower risk of peripheral arterial disease in patients treated with imatinib vs. nilotinib or patients with CML treated without TKIs, suggesting a possible protective role of imatinib in atherosclerotic vascular diseases (10). The supposed mechanisms related to nilotinib cardiovascular toxicities are complex and may involve different pathways. Nilotinib may lead to overexpression of cell adhesion proteins on human endothelium, including ICAM1, VCAM1, and E-selectin, which may enroll inflammatory cells and platelets and increase the risk of cardiovascular events (14). Nilotinib also represses endothelial cell proliferation and migration and may inhibit other kinases related to angiogenesis (17). In our study, in line with previous data, we have also observed a higher risk of cardiovascular disease, including cerebrovascular and ischemic heart disease or myocardial revascularization, in patients with nilotinib when compared with imatinib, even excluding patients with a past history of heart and cerebrovascular disease and adjusting the analysis for baseline cardiovascular risk factors.

The risk of cardiovascular ischemic events induced by dasatinib is not well-established. Despite the higher incidence of cardiovascular events in patients treated with dasatinib in relation to imatinib (4 vs. 2%) at the 5-year follow-up of the DASISION trial (8), a *post hoc*

analysis that included patients from the DASISION trial showed that the cardiovascular events occurred mainly in patients with a history of cardiovascular disease (18). In a retrospective study that analyzed data from 105 patients with CML in Polish tertiary health centers, patients treated with dasatinib had lower rates of vascular events (4%) than patients with nilotinib (11%) (19). We showed in our analysis a lower HR of cardiovascular and cerebrovascular events in patients with dasatinib compared to imatinib, differing from other analyses by being a real-world cohort and excluding patients with overt cardiovascular and cerebrovascular diseases before the start of a TKI. It is also essential to keep in mind the TKIs used for CML treatment differ in their potency and activity against BCR-ABL1 and other kinases, which also exert relevant functions on the cardiovascular system. This can in part explain the observed discrepancy in the cardiovascular risk between the different TKIs.

A warning signal for the risk of heart failure in patients with CML treated with BCR-ABL TKIs was suggested in 2006 by Kerkelä and colleagues when reporting a case series of 10 patients treated with imatinib that had developed heart failure with reduced LVEF. Myocardial biopsies in two patients and three imatinib-treated mice showed mitochondrial abnormalities and accumulation of membrane whorls in both vacuoles and sarcoplasmic reticulum, suggesting toxic myopathy possibly associated with ABL inhibition (20). However, a further follow-up study of patients treated with imatinib did not demonstrate a higher risk of heart failure or cardiomyopathy (21). In our cohort, the unmatched incidences of the composite outcome

heart failure or LVEF < 50% were higher in the imatinib group (1.83%) and the nilotinib group (3.1%) than in the dasatinib group (0.78%). After matching for baseline risk factors, patients treated with imatinib showed a greater ratio for heart failure or a reduced LVEF than patients with dasatinib but not in relation to patients with nilotinib, suggesting that in a long term, dasatinib may exert less toxicity on ventricular function than imatinib or nilotinib. However, we should take into account that heart failure incidence was low in the three treatment groups.

In our study, patients with CML who were switched from one TKI to another were excluded from the analysis. One might question that patients on dasatinib who stopped medication for pleural effusion, which is a common adverse event with this medication, might have a higher incidence of heart failure and lead to a selection bias. However, the physiopathology of pleural effusion in patients treated with dasatinib is not related to heart failure, given that dasatinib-induced pleural effusions are generally lymphocyte-predominant exudates (22). In addition, data indicate dasatinib-induced pleural effusion could be related to strong inhibition of the platelet-derived growth factor receptor  $\beta$ , leading to a decreased interstitial fluid pressure and higher vascular permeability (23).

Venous thromboembolic events have not been described as a significant adverse effect of BCR-ABL TKIs. An exception was a phase 2 study that included patients with CML for ponatinib treatment, which showed moderate rates of VTE, mostly deep vein thrombosis and pulmonary embolism, that occurred in 5% of patients (24). In our study, the overall incidence of VTE or pulmonary embolism was low in the three TKI groups, and we have not observed a difference in risk between them.

The strengths of this study are the sample size, considering the low incidence of CML in many healthcare organizations, the capacity of adjusting the outcomes for baseline cardiovascular characteristics, and the real-world essence of the data. We must recognize several limitations of this study. First, it involved analyses of a retrospective observational cohort, which led to baseline differences among the treatment arms, such as older individuals with more cardiovascular risks in the imatinib group. This fact led us to use propensity score matching, which may have some problems like trying to mimic a randomized experiment, without the same precision and control against confounding. Also, propensity score matching may create a “propensity score paradox,” in which unit pruning causes increased imbalance after a point (25).

Due to its observational retrospective nature, the study may be inherently subject to bias. Therefore, we should carefully avoid making cause–effect relationships and, instead, consider the results as a hypothesis generator. Second, despite the matching, we cannot exclude the influence of residual confounding, which was not captured, such as TKIs and cardiovascular medications dosage, administration timing since the beginning of the follow-up, and lifestyle habits such as physical activity and diet. Particularly TKI dosage may be an important factor for cardiotoxicity as showed in the ENESTnd trial, in which a higher dosage of nilotinib was associated with a higher incidence of arterial events in relation to a lower dosage or with imatinib (15). We were also unable to analyze the treatment discontinuation rates for the three BCR-ABL TKI groups, which could influence the timing of exposition to the TKI and their cardiovascular effect. Third, the outcomes and baseline characteristics were based on 10 ICD codes, which are not accurate when compared with adjudicated outcomes in randomized clinical trials.

In conclusion, we found in a large sample of patients with CML treated with BCR-ABL TKIs that when compared with imatinib treatment, patients treated with nilotinib had a higher ratio of ACE, while patients treated with dasatinib showed a lower ratio of cardiovascular and cerebrovascular events. The ratio of heart failure was greater in patients with imatinib when compared to dasatinib but not compared to nilotinib. These results raise the hypothesis that, when comparing three commonly used BCR-ABL TKIs, nilotinib presents a higher probability of cardiovascular toxicity and dasatinib presents a better cardiovascular safety profile. These findings may be particularly relevant in patients with CML and underlying cardiovascular risk factors, in which a BCR-ABL TKI is being considered for treatment.

## Data availability statement

The original contributions presented in this study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

## Ethics statement

The studies involving human participants were reviewed and approved by Comissão de Ética em Pesquisa do Hospital Alemão Oswaldo Cruz. Written informed consent for participation was not required for this study in accordance with the national legislation and the institutional requirements.

## Author contributions

All authors listed have made a substantial, direct, and intellectual contribution to the work, and approved it for publication.

## Acknowledgments

We thank Hospital Alemão Oswaldo Cruz for the access to the collaborative research network TriNetX.

## Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
